ABSTRACT
Hot water injection is a production technique proposed to gas recovery from methane hydrate reservoirs. However, from a practical point of view, the injected water experiences a drop in temperature and re-formation of hydrates may occur in the reservoir. In this work, we proposed a model expressing permeability hysteresis in the processes between hydrate growth and dissociation, and studied hydrate dissociation behavior during hot water injection. The model of permeability hysteresis was incorporated into the simulator MH21-HYDRES (MH21 Hydrate Reservoir Simulator), where the decrease in permeability with hydrate saturation during hydrate growth process was assumed to be much larger than the decrease during hydrate dissociation process. Laboratory hydrate dissociation experiments were carried out for comparison. In each experiment, we injected hot water at a constant rate into a sand-packed core bearing hydrates, and the histories of injection pressure, core temperature, and gas/water production rates were measured. Numerical simulations for the core experiments showed the re-formation of hydrates led to the increase in injection pressure during hot water injection. The simulated tendencies of pressure increase varied markedly by considering permeability hysteresis. Since the experimental pressure increases could not be reproduced without the permeability hysteresis model, the influence of permeability hysteresis should be considered to apply hot water injection to hydrate reservoirs.

**NOMENCLATURE**

- $A_g$: Specific surface area of gas particles [0.375 mm$^2$]
- $A_{HS}$: Specific surface area of hydrate particles [0.375 mm$^2$]
- $C$: Specific heat [J·kg$^{-1}$·K$^{-1}$]
- $D$: Depth from a reference level [m]
- $f_g$: Gas fugacity at V-H-L$_w$ equilibrium [MPa]
- $f_w$: Gas fugacity in pore space [MPa]
- $g$: Acceleration of gravity [9.80665 m$^2$·s$^{-2}$]
- $h$: Enthalpy [J·kg$^{-1}$]
- $K_{hi}$: Hydrate dissociation rate constant [mol·m$^{-3}$·MPa$^{-1}$·s$^{-1}$]
- $K_{gen}$: Hydrate formation rate constant [0.31 mol·m$^{-3}$·MPa$^{-1}$·s$^{-1}$]
- $K_{p}$: Absolute permeability [m$^2$]
- $K_{p0}$: Absolute permeability at $S_w=0$ [m$^2$]
- $k_{rl}$: Relative permeability to phase (l) [fraction]
- $k_{rw}$: End-point water permeability [fraction]
- $k_{rg}$: End-point gas permeability [fraction]
- $m$: Power of (1 – $S_w$)
- $N$: Permeability reduction index
- $N_{hys}$: Permeability reduction index during hydrate re-formation / dissociation
- $n$: Power of $S_w$D
- $\dot{n}$: Net generation rate of component (i) per 1m$^3$ of sediment during hydrate dissociation /formation and water freezing/ice melting process (i = CH$_4$, H$_2$O) [mol·s$^{-1}$·m$^{-3}$]
- $\dot{n}_{lime}$: Generation rate of component (i) due to hydrate dissociation per 1m$^3$ of sediment (i = CH$_4$, H$_2$O) [mol·s$^{-1}$·m$^{-3}$]
- $\dot{n}_{prod}$: Production rate of phase (l) per 1 m$^3$ of sediment [mol·s$^{-1}$·m$^{-3}$]
- $p$: Pressure [Pa]
- $Q_{hi}$: Heat sink rate due to hydrate dissociation per 1 m$^3$ of sediment [W·m$^{-3}$]
- $Q_{i}$: Heat sink rate with ice-water phase transition per 1 m$^3$ of sediment [W·m$^{-3}$]
- $Q_{salts}$: Heat generation rate with salt dissolution into water per 1 m$^3$ of sediment [W·m$^{-3}$]
- $Q_{ext}$: Heat sink rate to outside at the system boundary per 1 m$^3$ of sediment [W·m$^{-3}$]
- $\dot{Q}_{prod}$: Heat sink rate with production of phase (l) per 1 m$^3$ of sediment [W·m$^{-3}$]
- $R_{inj}$: Injection rate of hot water [ml/min]
- $S_{H_{hys}}$: The hydrate saturation at the reformation
- $S_{H_{norm}}$: The normalized hydrate saturation in reformation / dissociation process
- $S_{iw}$: Irreducible water saturation [fraction]
- $S_i$: Saturation of phase (l) [fraction]
- $S_{g}$: Residual gas saturation [fraction]
- $T$: Temperature [K]
- $T_{inj}$: Temperature of injected water [K]
- $t$: Time [s]
- $U$: Internal energy [J·kg$^{-1}$]
- $x_i$: Mole fraction of component (i) in water phase (i = MeOH, salts) [fraction]
- $\phi$: Porosity [fraction]
- $\lambda_{eff}$: Effective thermal conductivity of sediment, [W·m$^{-1}$·K$^{-1}$]

**INTRODUCTION**

Methane hydrate is a crystalline solid composed of water and methane. The total amount of methane gas in this solid form may surpass the total conventional gas reserve. And some individual methane hydrate accumulations may contain significant and concentrated resources [1]. That indicates the potential as a future energy resource. Hot water injection is one of gas production methods from hydrate reservoirs [2]. In this study, we considered that the permeability change by hydrate re-formation and gas production change by hydrate dissociation and concluded that the permeability changed rapidly when the hydrate saturation exceeded a threshold [3] [4]. In this study, we considered that the permeability change has hysteresis in the processes between hydrate formation and dissociation. We modeled the permeability hysteresis and incorporated the model into the original developed simulator: MH21-
HYDRES (MH21 Hydrate Reservoir Simulator). Thorough the comparison between numerical simulation and experimental data, the permeability hysteresis model was validated.

THEORY OF SIMULATOR

Governing equations

The MH21-HYDRES is a compositional simulator solving the equations of mass balances for methane, water, methanol and salts, and one energy balance equation. The mass and energy balances equations are as follows:

Mass balance equations:

For methane components:

\[ \nabla \left( \frac{k_D k_m \rho_g}{\mu_g} \left( \nabla p_g - \bar{p}_g g \nabla D \right) \right) + \frac{\partial}{\partial t} (\rho_g \phi S_g) = 0 \tag{1} \]

For water components:

\[ \nabla \left( \frac{k_D k_m \rho_w}{\mu_w} (1 - x_{MeOH} - x_{salts}) \left( \nabla p_w - \bar{p}_w g \nabla D \right) \right) + \frac{\partial}{\partial t} (\rho_w \phi S_w (1 - x_{MeOH} - x_{salts})) = 0 \tag{2} \]

For methanol components:

\[ \nabla \left( \frac{k_D k_m \rho_w x_{MeOH}}{\mu_w} \left( \nabla p_w - \bar{p}_w g \nabla D \right) \right) - x_{MeOH} \frac{\partial}{\partial t} (\rho_w \phi x_{MeOH} S_w) = 0 \tag{3} \]

For salts components:

\[ \nabla \left( \frac{k_D k_m \rho_w x_{salts}}{\mu_w} \left( \nabla p_w - \bar{p}_w g \nabla D \right) \right) - x_{salts} \frac{\partial}{\partial t} (\rho_w \phi x_{salts} S_w) = 0 \tag{4} \]

Energy balance equation:

\[ \frac{\partial}{\partial t} \left( (1 - \phi) \bar{p}_g C_p T + \phi \left( \sum_{j=H,salts} S_j \bar{p}_j C_p T + \sum_{j=g,salts} S_j \bar{p}_j U_j \right) \right) = \nabla \cdot \left( \lambda_{eff} \nabla T \right) + \nabla \cdot \left( \sum_{i=w,g} k_i k_j \bar{p}_j \left( \nabla p_i - \bar{p}_i g \nabla D \right) \right) - \dot{Q}_H - \dot{Q}_{ salts} - \dot{Q}_{ sat} + \sum_{j=w,g} \dot{Q}_{ prod,j} \tag{5} \]

Permeability hysteresis during hydrate re-formation / dissociation

The permeability of hydrate reservoirs can change due to presence of hydrates. Masuda et al. have proposed a following model to express this phenomenon [5].

\[ k_p = k_{D0} \left( 1 - S_H \right)^N \tag{6} \]

In dissociation process, as is common in depressurization method, this model is supported by experimental data [6]. On the other hand, in re-formation / dissociation process, the permeability can change more rapidly than that of just dissociating process. We modeled this rapid change of permeability as:

\[ k_p = k_{D0} \left( 1 - S_{H_{sys}} \right)^N \left( 1 - S_{H_{norm}} \right)^{N_{sys}} \tag{7} \]

\[ S_{H_{norm}} = \frac{S_H - S_{H_{sys}}}{1 - S_{H_{sys}}} \tag{8} \]

where \( S_{H_{sys}} \) is the hydrate saturation at the re-formation and \( S_{H_{norm}} \) is the normalized hydrate saturation in re-formation / dissociation process. In this model, the permeability reduction index of re-formation/dissociation process \( N_{sys} \) is larger than \( N \) in Eq. (6). Figure 1 shows this permeability hysteresis in the processes between hydrate formation and dissociation.

Relative permeability

The gas and water relative permeabilities were modeled as follows:

![Figure 1 Permeability reduction ratio vs. \( S_H \).](image-url)
Gas relative permeability:

\[ k_{rg} = k_{rg}^0 (1 - S_{wD})^n \]  \hspace{1cm} (9)

Water relative permeability:

\[ k_{rw} = k_{rw}^0 S_{wD}^m \]  \hspace{1cm} (10)

\[ S_{wD} = \left( \frac{S_w - S_{iw}}{1 - S_{iw} - S_{rg}} \right) \]  \hspace{1cm} (11)

Figure 2 shows the gas and water relative permeability curves used for this study. Parameters in Eq. (9) and (10) were set as Table 1. Residual gas saturation was used as a matching parameter for gas production.

**Hydrate formation / dissociation**

Clarke-Bishnoi equation was used to model hydrate dissociation [7].

\[ \dot{n}_{\text{dissoc}, CH_4} = K_{\text{g}} \phi S_H A_H \left( f_e - f_g \right) \]  \hspace{1cm} (12)

**EXPERIMENTAL**

**Apparatus and procedure**

Artificial methane hydrate cores were prepared for experiments. The core length and diameter were 150 mm and 50 mm respectively. The core was packed into the rubber sleeve. The rubber sleeve thickness was 10 mm. The core holder as shown in Figure 3 was used for the dissociation experiments. The core was maintained at constant pressure and temperature. Hot water was injected from one side of the core and the pressure of the other end was kept constant. Figure 4 shows the position of the sensor. The volumes of gas and water produced, temperatures of inside and outside of the core and pressures at the both ends of the core were measured.

![Core holder](image)

**SIMULATION DETAILS**

**Grid system**

A cylindrical coordinate system was used. The hydrate core and rubber sleeve were divided into 7 x 30 grids. Figure 5 shows the schematic grid
system. Boundary conditions such as heat transfer were set to reproduce the experimental conditions.

Model settings
Parameter studies (Run 1-3) and comparison studies (Run e1, 2) were conducted. These simulations have differences in models: re-formation and hysteresis models are considered or not. Table 2 shows the model differences between these simulations.

RESULTS AND DISCUSSION
The effect of hydrate re-formation and permeability hysteresis
We studied the effect of hydrate re-formation and permeability hysteresis using parameter studies with three different conditions (Run 1-3). Figure 6 shows the comparison of injection pressures of these three Runs. Through the comparison between Run 2 and Run 3, it was found that the reduction of differential pressure was delayed due to re-formation of hydrates. But the value of differential pressure was almost the same whether hydrates re-form or not. On the other hand, in Run 1 with permeability hysteresis, the differential pressure increased and decreased rapidly since the processes between re-formation and dissociation of hydrates caused rapid change of permeability. The comparison of cumulative gas produced in Figure 7 shows that re-formation and permeability hysteresis had a limited effect on gas productivity as long as hot water could be injected. However, the large injection pressure may be critical problem for application of the method.
Comparison between the simulation and the experiment

We conducted comparison study between the simulation and the experiment. Injection pressure, cumulative gas produced and temperatures of inside of the core were compared. Figure 8 shows the comparison of injection pressure. Measured injection pressure showed the rapid increase and decrease. The simulation with permeability hysteresis model (Run e1) reproduced the rapid change of the injection pressure. In contrast, the simulation without permeability hysteresis model (Run e2) could not reproduce this tendency. In the experiment, reductions of injection pressure were seen at 35 min and 55 min. It was considered that heterogeneity of the core caused the some reductions. Figure 9 shows the comparison of cumulative gas produced. The difference among models was not obvious, however, the simulation with the permeability hysteresis model reproduced the measured data. Figure 10 shows the comparison of temperatures of inside of the core. The simulation with permeability hysteresis model reproduced the tendency of measured data. Figure 11 shows the profiles of hydrate saturation, gas saturation, pressure and temperature at 20 min, 50 min, 100 min and 200 min. In Figure 11, hot water was injected from the left end of the core. Hydrates were dissociated from left to right side of the core and re-generated at low temperature region. At 50 min when the injection pressure reached maximum value, hydrate saturation rose up to 0.79, and pressure dropped rapidly in hydrate saturated region. At 100 min when the injection pressure dropped to initial value, hydrates of center of the core disappeared and gas broke through the core.

Figure 9 The comparison of cumulative gas produced.

Figure 10 The comparison of temperatures.

Figure 11 The profiles of hydrate saturation, gas saturation, pressure and temperature.
CONCLUSION
We modeled permeability hysteresis in the processes between formation and dissociation of hydrates. Developed model was incorporated into the simulator: MH21-HYDRES, and a comparison study between simulation and experiment was conducted to validate the model. The simulator with permeability hysteresis model reproduced the rapid change of injection pressure measured by the experiment. Injection pressure increased to a value a few MPa higher than the initial pressure since re-formation of hydrates caused permeability reduction. Simulations showed that re-formation and permeability hysteresis had limited effect on gas productivity as long as hot water could be injected. However, the large injection pressure may be a critical problem for application of the method.

ACKNOWLEDGMENT
This work was done as a research project under the Research Consortium for Methane Hydrate Resources in Japan (MH21 Research Consortium) on the National Methane Hydrate Exploitation Program by the Ministry of Economy, Trade and Industry (METI). We would like to thank the Ministry of Economy, Trade and Industry (METI) who financially supported this research.
