## ABSTRACT

A parser for English sentences using case and an augmented transition network is described. The interaction between syntax, semantics, and case is examined with special emphasis on their role in this particular system. The thesis concludes with a re-affirmation of the inseparability of syntax and semantics. and with cautious optimism for the future cf case in computational linguistics.

has a way to betray
the revolution
This is mine

I fought in the old revolution on the side of the ghost and the king Of course $I$ was very ycung and $I$ thought that we were winning I can't pretend $I$ still feel very much like singing as they carry the bodies away
-I. Cchen

## SECTION 1. 1: Introduction

The work described in this paper was largely inspired by Roger Schank's [11] work with Conceptual Lependancy Networks, although it is not intended to be an implementaticn of his ideas. It is a parser which uses the notion of case in its breakdown of a sentence, and which labels sentence parts with case names in the structure that it returns. The syster is written in LISP and it runs at the oniversity of British Columbia on an IBM 370-168 under the MTS operating system.

Case is a much more intuitive apprcach tc language than transformational grammars are. It not only demands the integration of semantics into the parser, but it makes it obvious that this is where the semantics belong. Case at least partially unifies these long separated components of language.

## SECTION 1.2: $\mathfrak{A}$ Brief Look at Soge Geleyant Case Systegs

Since Fillmore [6] wrote bis paper "The Case for Case" in 1968 there has been a strong movement in computaticnal linguistics towards a case analysis of the English language. Very briefly, fillmore introduced a notion of defp case in which a simple sentence is composed of $\begin{gathered}\text { verb with certain froferties }\end{gathered}$ such as tense, aspect, etc., and a set of noun phrases lakelled with case names. Fillmore does not give an exhastive list of the deep cases in English, but he does list a few cases that be views as essential. They are: agentive, dative, INSTRUMENTAL, factitive, locative, objective, and efnefactive. verbs are classified by their case environments, that is, by the set of cases they accept.

In 1972 celce-murcia [3] proposeda case system of five cases: CASUAL-ACTANT, THEME, LOCUS, SCURCE, and GOAL. Simmons [13] has written a system based on Celce-Murcia's theory. He classifies all, verbs into what he call "paradigms" according to the way the five cases may be arranged with the verb in the surface structure. He gives the example of the verb "to break". It belongs to the "ergative" paradigm which allows four case patterns.in the surface structure in the active voice:
(1.1) John broke the window with the hammer.
(1.2) John broke the window.
(1.3) The hamer broke the window.
(1.4) The window troke.

They can all be generated from the structure:
break: CASUAL-ACTANT1: John
THEME: window
CASUAL-ACTANT2: hammer
with the appropriate deletions and re-arrangements allowed ergative verbs. If enough verbs can be so classified, this provides a simple, yet apparently foverful mechanism for generating language. Using this scheme. for parsing, however, leads to the usual problems case systems have. In sentence (1.4) what is the CASUAL-ACTANT1, the AGENT in my terminclcgy? What is the CASUAL-ACTANT2, my INSTROMENT case? The system may be able to tell from context, or to make an intelligent guess. I do not mean to imply that these are problems particular to Simmon's work. They are not. His paradigm idea is very useful in that it limits to four the number cf possible arrangents of these three cases for ergative verbs.

The basic problem with using only five cases is that information which is fairly readily available in the surface structure tends to become obscured, if not lost. In sentence (1.1). for instance, we can infer a lot of information not explicit in the sentence. For instance, we guess that John
performed some act which caused the hammer to strike, and thus to break through the pane of glass in the window. Ee protably held the hammer in his hand and struck the window with its metal head, but he could have thrown it through the window; he cculd have struck the window sill or frame thus causing the pane to break, etc.

It is this more general picture that schank tries to build up with his conceptual dependancy nets. Schank employs fourten verbal primitives, or ACTs, and at least fcur cases (OBJECTIVE, RECIPIENT, DIRECTIVE, and INSTRUMENTAL) to build up a structure of primitives which captures the "meaning" of the sentence. I say "at least four cases" because other cases such as AGENT are implicit in his structures.
(1.5) John grew the plants with fertilizer.

For instance, from sentence (1.5) he builds the structure in figure 1.

Figure 1 - An Example from Shank

Notice that "fertilizer" appears to be in the instrument case in the surface structure, but it is in fact the cbjective
case of the $A C T$ "trans". Schank's structures cafture more of the meaning of the sentences than fillmore's deep structure do. Currently at MIT Xartin [9] is building a case system for the MAPL project. He has proposed a set of some thirty cases.

SECTION 1.3: A TOp=level Descripticn

The basic objective in this thesis was to explore the use of case in a system which parsed English sentences into a structure like Schank's conceptual dependancy networks. A lcose and incomplete set of verbal primatives were used instead of Schank's fourteen primative ACTs because they $s \in \in \mathbb{m} \in \mathbb{C}$ more intuitive. $\nabla \in \mathrm{rbs}$ like "buy", "sell", "give", "take", "steal", etc., are represented by "trans"; verbs like "go", "come", "run", and "leave" by "move"; and socn.

An important feature of case which Simmons does not acknowledge is that Fillmore's "case frames" can be used to select, from the multiple meanings of a verb, its intended meaning in the sentence. The procedural definiticn of a verb in my dictionary consists of a list of case frames which distinguish verb meanings.
(1.6) John stole the jewel.
(1.7) John stole into the building.

For instance the two meanings of the verb "to steal" in sentences (1.6) and (1.7) are distinguished ty the two case frames for the verb. The case frame for the meaning used in (1.6) demands a patient, wile the one for (1.7) requires a locative phrase with an adverbial preposition. This notion is used in a similar way by Schank.
(1.8) He stole.

Sentence（1．8）is ambigucus to $⿴ 囗 十 y y s y s t e m$ since the case frames for the verb cannot tell which meaning is intended．The system must resort to context，as you and $I$ do，to resolve the ambiguity．This mechanism has not been programmed，so currently the system will return the first meaning it succeeds on，which， after several failures to find a patient cr a locative fhrase， will be＂to thieve＂．

The rest of this chapter will be devoted tc a simple description of the control structure in which these case frames operate．

The system takes the sentence and tries to fit it into one of the frames，that is，it tries to find which meaning is being used in the sentence by looking at the sentence structure，its parts，and their semantic categories．If it gees through all of the meanings without finding one that．fits the sentence，it weakens its tests on the semantic categories，and then tries all of the meanings again．
（1．9）The turnip play $\mathrm{d}_{\mathrm{d}}$ a wild dance on the violin．

In sentence（1．9），for instance，the system will at first fail to find an agent because all of the case frames for＂to play＂ demand an animate，if not human，agent．These tests will be weakened，however so that on the second，or third time thrcugh the list of case frames a meaning will be selected．This process of going through the case frames again with weaker tests is refered to as the top－level back－up，althcugh it is not really back－up in the usual sense，since decision points are not
stacked and backed-up through on failure.
This was done for a specific reascn. Since the case frames are tried in order, the ordering can be used to help disambiguate the verb. In defining the second case frame for a verb, for instance, it is often useful to use the fact that ite first case frame has failed.

If the system backs up into this second frame with a weaker test, however, it may not be true that the first case frame would fail on the weaker test.

Another reason for not backing up in the usual sense, is for efficiency. Since the case frames are tried in order, obviously the most common verb usages should be put first in the list. If all of the meanings fail beacuse the tests are too severe, one still wants to try the most common meaningsfirst with the weaker tests.

Once the system has succeeded on a particular meaning of the verb it will proceed to look at the rest of the sentence nct already looked after by the framing frccess. Here a genuine back-up mechanism is employed. If the system thinks it has the correct case for a particular sentence part, it stacks a form to put the corresponding sub-structure into the main structure of the parse. If the rest of the sentence is handed ccrrectly, when the stack is unwound at the end, all of the forms so stacked are EVALed, and these sub-structures are put in. If, on the other hand, the system fails later on in the parse, it will back up to this decision point and lock for ancther way to handle this particular sentence part.

## CHAPTER 2

They will never ever reach $t h \in$ roon at least not the one that they're after

It is floating broken on the open $s \in a$ and it carries nc survivors
-I. $\quad$ Cchen

## CASES

The question of how many cases we need to describe English is a contentious one. As mentioned above, fillmore is vague cn the issue, whereas Celce-Murcia claims that five cases will do. The purpose of this work is to capture as much of the $\boldsymbol{m} \in \mathrm{aning}$ of a sentence as is possible, and to make it explicit in a formal structure. Case, then, is an explanation of the semantic function of a sentence part, so a fairly.large number of cases have been used, one for each of these "semantic functions". We are not adamant about our set of cases. The system is flexible and structured enough, that the addition or deletion of cases is a simple operation.

The system was originally designed with Martin's thirty-odd cases as its basis. There are currently twenty-fcur general cases implemented, plus numerous verb-specific cases. Some of Martin's cases have been dropped completely, some have simply not been implemented yet, and several have been added.
fairly self-explanatory. With each case is a set of examples (mostly from Leonard Cohen, if they seem strange) with the case in question underlined. Those cases which are flagged by certain prepositions have these prepositicns listed.

## SECTION 2.1: List of Cases

## Agent

The man in white says he has no friends.
The trees are burning in your promised land.
I got wiped out by several charismatic holy men. Love calls you by your name.

## Patient

He trained $\mathfrak{a}$ hundred gogen just to kill an unborn child.

You can read their address by the moon.
I am punished by your sclitary truth.
I washed ㄸy eyelids in the rain.

## Location

A scalpel blade lay beside my sily yer spoon.
Your letters all say that you are beside me now.
I sleep beneath the golden hill.
In city and in forest our steps will always rhyme.
I have lain by this windoy long encugh.
Flagged by at, in, on, by, near, beside, before, beneath, upcn.

Tinge
I love ycu in the morning.
If by chance $I$ wake at night and ask you who I am.
I suppose that he froze when the wind took your clothes.

We all should study etiquette before we study magic.
She fell in love for us in 1961.
Flagged by at, in, on, by, near, during, before, after, when, while, around.

## Recipient

She said that you gave it to her.
They brought me their comfort.
Flagged by to.

## Source

We will come from the shadows.
Thanks for the trouble you took from her eqes.
Taking from his wallet an old scheduel
of trains, he'll say. "I tcld ycu when I came I was a stranger."

Flagged by from.

## Destination

I will let you take me home.
Into this furnace $I$ ask you now to venture.
She leads you to the river.
Take me to the slaughterhouse.

Flagged by to, into, onto, toward, towards.

Duration
You have lived for years for nothing.
He will sleep for one night with the woman he flans to abandon.

They played their game in two hours.
Flagged by for, in.

## Instrument

She touched your perfect body with hel mind.
Cover up your face with scap, now ycu're Santa clause.
The infant with his cord is hauled in like a kite. Flagged by with.

Manner
They left in $\mathfrak{a}$ hurry.
I walk with my mouth shut into the drifting world.
I choose the rooms that $I$ live in with care.
I am eating a juicy peach by lamplight.
Flagged by in, with, by.

## Path

We started up the mountain.
Through the graves the wind is bloving.
I journeyed down a hundred steps.
we poured across the border.
Flagged by by, about, along, up, down, arcund, acrcss.

Method
I do not intend to save you any work $k y$ keeping silent.

Some men find strength by going their lonely ways. Who would have foretold that the heart grows old
from touching others.
Flagged by by, from.

## Expected=effect

I am only whispering to my tomahawk sc the image itself will reduce you to scorn.

They blamed Mitchell so the peofle wculd nct susfect them.

Flagged by so.

## Quantity

What is grey and comes by the guart?
We produce oil by the barrel and sell it ky the cup. Flagged by by.

## Exchange

I bought it with a nickle and $I$ sold it for a dime.
He wants to trade the game he plays for shelter.
You could not trade them for priesthood.
They are waiting to see a signal that some killer will be lighting for pay.

Flagged by with, for.

Beneficiary
I fought every man for her until the night was cuer.
I sing this to the crickets, I sing this
for the army.
I forgot to pray for the angels,
and so the angels forgot to pray for us.
Flagged by for, to, before.

## Conagent

I went with the one who found me.
I lived with a child of snow.
Nancy wore green stockings, and she slept
with eytryone.
Oh, come with me my little cne.
Flagged by with.

Descriptive (A case of the Ncun)
Suzanne takes you down to her place near the river.
The woman in blue is asking for revenge.
The hand of your beggar is burdened down with money. Flagged by of, from, at, in, on, with, by, near, beside, before, after, along, up, down, arcund, across, under.

Topic
It is time we began to laugh abogt it all again.
Lets not talk of love or chains.
Sometimes $I$ find $I$ get to thinking $\underline{c}$ the gast.
Flagged by of, about.

Canse
It rained so I got wet.
Flagged by sc.

## Puㄷpose

You who build these alters to sacrifice these children, you must not do it any more.

You were traning with mirrors to make
yourself perfect.
I lit a thin green candle to make ycu
jealous of me.
Flagged by to.

Enable
He robbed the bank so he and his wife could have separate holidays.

I had to kick you down the stairs so $\operatorname{I}$ could Savour uneqployment once again.

He have to put her away so we can get back tc the war. Flagged by so.

Like
He sank beneath your wisdcm like a
 Choir, I have tried in my way to be free.

The sun pours down like honey on our lady of the morning.

Flagged by like.

## 브는

The rcom just filled up with mosguitos.
He locked himself in a library shelf
with the details of gur honey=Igcn.
Flagged by with.

With most of the cases above is listed the prepositions that flag each case. This is a gross over-simplification of the relationship between verbs, prepositions, and cases. A preposition which flags one case for cne verb may very well flag ancther case for a different verb.
(2.1) I walked about the room.
(2.2) I talked about the room.

For verbs of movement like "walk", "about" flags the path case as in (2.1), but for verbs of communcaticn like "talk", it usually flags the topic case as in (2.2). . Martin notes this and proposes for each verb meaning to list all of the casesflagged by each preposition. Since there is a great deal of uniforifty across verbs in this regard, however, it wuch more efficient to set up a master table for all verbs in the system, then for $\mathfrak{f a c h}$ verb, to list only the irregularities.
(2.3) The scandal was whispered about the room.

Sentence (2.3) illustrates that "abcut" can flag the fath case for a communication $v \in r b_{\text {, }}$ so we dc nct want to rule cut the path case, we just want topic to be tried first. In (2.3) the topic slot will already be filled by "the scandal", so topic will be rejected, and the path case will be tried next.

This foregrounding of cases is specified by the perscn who
writes the dictionary. He may specify that for the verbs talk, laugh, whisper, etc., the occurrence of the preposition "abcut" should trigger the topic case before the path case.

There is another obvicus way of determining case names for prepositional and noun phrases. Consider the sentences:
(2.4) Fred bought the car for Mary.
(2.5) Fred bought the car for one dollar.

The preposition "for" flags many cases. In (2.4) it flags the beneficiary case, and in (2.5) it flags the exchange case. Associated with each case is a test which a phrase must pass to be accepted as that case. In the beneficiary case the test is:
(MUST-BE ANIMATE)
indicating that the beneficiary has to be animate, wile the test for the exchange case is:
(NOT (SHOULD-BE HUMAN ABSTRACT))
indicating that one usually dones not exchange something for a person or something abstract. These tests correctly sort out the cases in sentences. (2.4) and (2.5).

In general tests on cases are very difficult to design adequately. What test would be appropriate for the topic case? What could not be talked, laughed, or cried about? Perhaps some complex verb and context dependant test cculd be concocted, but
one has not been designed for this system. The test for the topic case is therefore $T$. one must therefore be careful when invoking the topic case because it will always succéd.

The exchange case is almost as bad, Anything can be exchanged for something. The weak test
(NOT (SHOULD-BE HUMAN ABSTRACT))
is put in which will at first fail if a human or an abstract noun is the candidate, but will pass if nothing else sefms to fit either. This simpletest runs into problems with certain sentences.
(2.6) I paid a fortune for $\mathbb{m} \boldsymbol{y}$ mother's release.
(2.7) I paid a fortune for my wother.
(2.8) I paid a fortune for the prosititute.

It will initially force the exchange case to reject "for my mother!s release" in (2.6) because it is abstract, kut later cn it will accept it since all of the other cases flagged by "for" will also reject it. Sentence (2.7) is ambiguous, tut "mother" is almost certainly in the beneficiary role here, so again the test works correctly by rejecting the exchange case. Sentence (2.8) is also ambiguous, but our interpretation would usually be that "prostitute" is being used in the exchange case here. Tte system will, however, assign it the beneficiary case as it did in (2.7). Much work must be done on case tests if this paradigm is to be useful.

SECTION 2. 3: Verb=Specific Cases

The cases listed in SECTION 2.1 are general cases, alfost all of which can be asscciated with any verb. Many verbs, however also have special cases.

The verb "to be" is a prime example. In this system "to be" has eight meanings. Let's look at a few of them.

The third meaning of "tc be" is "tc have the property...". as in sentence (2.9).
(2.9) The house is red.

If you look at the entry for "to be" in the dictionary in APPENDIX IV you will see that this meaning is picked up ty the form:
((ADJ-LIST T) ADJ CBL (AGENT T) AG OEL)

The function ADJ-IIST looks for an adjective phrase. Sc an adjective phrase is considered to be a special case of the verb "to be".

The sixth meaning of "to be" is "to be frcm . . .", as in sentence (2.10).
(2. 10) The lady is from Ouagadcugcu.

This special case is locked for by the functicn Clade which takes as arguments a list of prepositions to look for, a test
that the prepositional phrase must pass, and a name for the case it is looking for. In this case the form is:
(CLADSE (FROM) '(MUST-BE COUNTRY CITY TOQN CONTINENT LOCATION)
'LOCATION) ${ }^{1}$

In other words: Look for a phrase starting with "from" which is a location of some kind.
(The third argument is needed for the back-up mechanism. It is possible to turn the MUST-BE tests cff for cnlycertain cases. This is useful when you are happy with the action cf all of the tests but those asscciated with a certain case cr two.)

My notion of case is rather general, in which an important function of a case is to distinguish betwen verb meanings. In the following chapter we will look carefully at just how cases are employed to do this.

1 Note that (MUST-BE LOCATION) will suffice as the test here, since COUNTRY, CITY, etc., all have the attribute LOCATION. The other categories are put in since they occur most often in this structure, and will thus speed up the sєarch. He comes from the West.". would also be handled since "West" would alsc bave the attribute LOCATION.

## SECTION 2. 4 : The Structure Returned

APPENDIX III gives a formal description of the structures returned by the system. This section will give a more informal and intuitive description. APPENDIX I gives lots of examples of these structures.

The basic idea was to return a structure which coulc be EVALed by LISP for further processing. The top-level function was to be " $<=\Rightarrow$ " wich would be an FEXER since it can take $a$ variable number of arguments. The first argument to $\Leftrightarrow={ }^{\circ}$ is the agent or subject of the verb. The "or subject" is necessary in cases like sentence (2.11) because some verb primitives, HayePROP in this case, allow $\Leftrightarrow=\Rightarrow$ to take sentences as a first argument.
(2.11) That I came is sillp.

The second argument $t c \Leftrightarrow$ is the tense of the $v \in r$.
The third argument is the predicate. This is alway a list beginning with the verb symbol "<--". The idea again was that this would be a form to ke Evaled. The first argument for-- is a verb-primitive. The second and third arguments are optional for some verbs, and not for others. The second is an adverbial phrase structure beginning with "<-ADV-". For instance,

Would have the structure:

$$
(<-- \text { MCVE }(<-A D V-\text { QUICKLY)) }
$$

If the verb takes a patient in the sentence, this patient follows the adverbial phrase if it is there, ctherwise it follows the verb primitive.

The rest of the arguments to $<\Rightarrow=$ are the cases of the verb, and any top-level adverbial phrases, like "well" in sentence (2.12).
(2.12) He played the piano well.

Their order is not considered important in the structure, so they just appear in a list at the same level as the verb symbol <-- The cases are lists beginning with an atom of the form

## <-CASE-

were CASE is replaced by any of the cases but agent, Patient, or DESCRIPTIVE. These three cases are treated specially. As mentioned abcve, the agent is the first, argument of <==>, and the patient is the last argument of $<-$. The $\operatorname{leSCRIPTIVE}$ case is a special case which is used to hande all of the prepositional phrases which modify nouns. This case, therefcre, is embedded in the noun-phrase structure. This is ade more explicit in CHAPTER 4.

## CHAFTER

3

> Thanks for the troukle
> you tcok from her eyes I thought it was ther for oocd sc $I$ never tried
> $-L . ~ C c h \in n$

## THE DICTIOKARY

Each word in the dictionary is set up as follcws:
(WORD I1 P1 I2 F2 .... In Pn)
where WORD is the word in questicn, and each pair (Ii Pi), i>0 is an indicator and a property which are to be fut on the property list of WORD. ${ }^{1}$

For each word, one of the indicators should be a part of speech. The property under this indicator is information for the morphology routines. For a noun, for instance, the property under $N$ indicates how the plural of the noun is formed; for verbs, the property under $V$ indicates how the first-person singular and past tenses are formed; etc.

On the property list of ncuns is a list of the noun's

[^0]properties under $\mathbb{N}$-PROP, its superset under SuPERSFT, and so on. For verbs cne puts a procedural definition of the verb under V-MEAN. To understand just how the system works it is necessary to see how these procedural definiticns work.

## SECTION 3.1: Verb Definitions

The verb is treated as the focal point of the sentence. A verb can have many meanings. The system discovers which meaning is intended by looking at the rest of the sentence. In so doing, it builds a structure representing a parse of the sentence.

Gith each verb, then, is associated a set of cases cf the verb, some cbligatory, some optional, and some concitionally optional. These cases are embedded in a form on the proferty list of the verb. Ample examples of verbal definitions can $k \in$ found in APPENDIX IV, but a careful lock at one in detail is necessary for an understanding of the system. In CEAFTFR 4 a long example is given showing just how these definitions work in parsing a sentence.

Consider the verb "to order." Its dictionary entry is as fcllows:

```
MORDER V
S-ED
    PREP-CASE ((WITH RITH))
        V-MEAN
        (IF ((AGENT (MOST-BE HUNAN))
            AG
                (OPT (GETR PASSIVE) SOMEONE)
                (PATIENT (MOST-BE ANIMATE))
            PA
                OBL
                (TO-COMP (GETR FA))
                TOC
                OBL)
                (BUILDQ ("<==>" ? "+" ("<--" ORDER "+")) AG TNS TCC)
                ((AGENT (MUST-BE HUMAN))
            AG
                (OPT (GETR PASSIVE) SOMEONE)
                    (PATIENT (AND (MUST-BE THING) (NOT (MOST-BE HUMAN)))
                    PA
            OBL)
            (BUILDQ ("<==>" ? "+" ("<--" CREER ?)) AG TNS PA)))
```

Figure 2 - The Dictionary Entry for the verb "tc order"

```
Onder the indicator V-MEAN you will see a form teginning
```

    (IF (IAGENT . : .
    IF is a function which takes an even, but otherwise variable, number of arguments, each pair representing a meaning of the verb. . The first element of each pair is a set of cases to be looked for, and the second is the structure to be built if they are found.

It is in the first element of the pair that the complexity lies. Let us look at it more closely.

The list of cases is, in fact, a list of triples. The first element is a form to be EVALed. It is usually lcoking for
a case, but any form is admissible. The second element of the triple is an atom: a register name. If the first form evals to a non-Nil value, the value is put into this register. In cur example, for instance, the first triple is:
(AGENT (MUST-BE HUMAN)) AG (OPT (GETR EASSIVE) 'SOMEONE))

The function of the first form is to find the agent of the sentence. If it succeeds, this agent is put intc register AG. The third element of the triple says wat to do on failure. If it is the atom "OBL", then this indicates that the case was obligatory, so if it was not found, then IF should fail on this meaning of the verb. If the atom is "OPT". then the case is optional, so the register is left.empty, and If continues with this meaning. The third possibility is that this third element is a form, in which case it is EVALed. If it returns "OEL" cr "OPT", then the result is as described abcve. If it returns anything else, then that is put into the register, and $1 F$ continues with this meaning of the verb.

Let us look at "to order" again. The third element of the first triple is
(OPT (GETR FASSIVE) 'SOMECNE)

OPT is a very simple function which, if its first argument is non-NIL, returns its second argument. Otherwise it returns "OBL".
is true if the sentence is in the passive vcice.
So the first triple can be read as follows:
Look for an agent which must be huran. If ycu find one, put it in register ag. Ctherwise, if the sentence is passive, make SOMEONE the agent. otherwise fail.

The second triple is more simple. It merely says: If you find an animate patient, then put it in register $P A$, else fail. The third triple is equally simple, but it is not looking for a case, but a to-complement. If these three elements are found in the sentence, then the system will look no further, but assume that it has found the correct meaning of the verb. It will EVAL the second forll of the pair: in this case:
(BUILDQ ("く==>" ? + ("<--" ORDER +)) AG TNS TOC)
which builds the basic structure for the sentence.
BUILDQ takes a variable nuaber of arguments. The first is a kind of template $u$ ith slots in it. The rest of the arguments fill the slots.

The "+" denotes a slot which is filled by the contents of a register.

The "?" Is filled by the applicaticn cf the function NOUN-POT to the contents of a register.

[^1]Finally, the "\#" indicates that $\begin{aligned} & \text { form is to te } E v A L \in d \text {, and }\end{aligned}$ the result put, into the slot. The slcts are filled in crder ty the second, third, $\in t c$, arguments.

So in this case:
(NOUN-POT (GETR AG)) is put in for the ?. (GETR TNS) in place of the first +. (GETR TOC) for the second +.

Where GETR returns the contents of a register.

You who build the alters now to sacrifice these cbildren you must nct do it any more A scheme is not a vision and you never have been tempted by a demon or a god
-I. Cchen

## AN EXBAUSTIVE EXAMPLE

Programming details tc not belong in a thesis of this kind. All of the code is in APPENDIX $V$ for those interested. In the following example, then, function names and excessive details will be, on the whole, left out. A detailed account of the basic algorithm and control structure will be given. We will look at a simple sentence. More complex structures such as relative and subordinate clauses are treated in much the same way as their parent sentences.

Consider the sentence:
(4. 1) The man beside the window played the fianc for Mary.

The first step in the process is a partial parse using an augmented transition network (ATN) as described ky wcods[15]. "Partial" is used bacause the parser is purely syntactic. The structural description usually associated with a parse is incomplete. That is, no decisions are $\mathbb{A}$ de about what modifies
what, what meaning of the verb is being used, etc. The basic idea behind the $A T N$ is to find the verb; but whif it is dcing this, it might as well chop the sentence up intc its parts. There are problems with just how this chopping should be done, but with most. sentences it is straight forward. A look at the sample parses in APPENDIX $I$ will give more examples of this notion.

The ATN parse returned will look like this:

S

$$
\mathrm{NP} \mathrm{NIL}
$$

DET THE
N MAN
NUMBER SG
PP NIL BESIDE
NP NTL
DET THE
N WI NDOW NUMBER SG
VP NIL
TNS
PAST
VOICE ACTIVE
V PLAY
NP NIL
DET THE
a PIANO
NUMBER SG
PP NIL FOR
NP NIL
NPR MARY

Figure 3 - An atn Parse of Sentence (4.1)

ATNS have been found to be a useful formalism for procedural definitions of grammars, but have been criticized for their slowness. Because this ATN returns such a simple
structure, however, it is very fast, and consumes little of the total time to process a sentence. It is on this preliminary parse that the program works.

First, the main verb is found, and a function is invcked which controls the top-level back-up. This functicn fVals the form on the property list of the verb under the indicator V-MEAN. This form for play is a very long one, so rather than reproducing it here, you are refered to the entry for play in the dictionary which is listed in AppencIX IV.

The form in question is a call to IF, whose mechanism has been briefly described in SECTION 3.1. In this case IF has eight arguments, indicating that there are four meanings to the verb PLAy in the system.

The first meaning is "to play a musical instrument."
The first case looked for is the AGENT. This agent shculd be a musician, and must be human. This search is made by Evaling the first form in the first triple of the first argument to IF:
(AGENT (AND (SHOULD-BE MUSICIAN) (MUST-BE EOMAN)))

AGENT is fairly complex, but basically it looks for a component of the $A T N$ parse (in future called the "p-parse", for partial-parse) which is in an appropriate position to $k \in$ an agent, and which passes the test (the argument tc AGENT.) By 'appropriate position' is meant, for instance, that if the sentence is in the active voice, the agent is frgbably the first noun phrase in the sentence.

In this case, AGENT immediately finds "the man" as the obvious candidate, and it applies the test
(AND (SHOULD-BE MUSICIAN) (MUST-BE HUMAN))

Now, unless something special has been put on the property list of MAN previously, the
(SHCUID-BE MUSICIAN)
part of the test will fail.
(There are two levels of tests in this system: SHOULD-BE tests and MUST-BE tests. This crude mechanism is very useful for forcing a verb like play to lock hard for a musician to flay an instrument -- but to accept any human if it fails at first. This is especially powerful for resolving anaphoric references.) So AGENT fails. This invokes the third element of the AGENT triple:
(OPI (GETR PASSIVE) SOMECNE)

This may be read as: AGENT is optional if the sentence is in the passive voice, in which case put SOMEONE in as the agent. Otherwise AGENT is obligatory. So, since the sentence is not passive, AGENT is obligatory. Since the AGENT case was not found, this first meaning of play fails.

So If goes on to the next pair of arguments. This pair is
designed to pick up the meaning of PLAY as in "tc play music." Note that the test on AGENT is just like the previous cne, so it will also fail.

So we go on the the third meaning of to PLAY: "to play a sport." Here the test on AGENT is
(AND (SHODLD-BE SPORTS-MAN) (MUST-BE HUMAN))

Once again, providing MAN does not have SPORTSMAN cn its property list, this meaning fails.

On to the fourth, and last, meaning. This is sort of a catch-all. It is just "to play" as in "tc entertain oneself." Here the test on AGENT is
(MUST-BE ANIMATE)
"The man" passes this test. (Note that in the dicticnary MAN has the property anIMATE under N-PROP)

Since $A G E N T$ is the only case locked for, this $\mathbb{I} \in a n i n g$ is taken to be the correct one, and the fcllowing structure is built by the call to BuIIDQ:

```
<==>
N MAN
            NUMBER SG
            <-DEFINITE- THE
PAST
<-- LO
<-CAUSE-
            <==>
                N MAN
                    NOMBER SG
                    <-DEFINITE- THE
                pRESENT
                <-- HAVP-PROP ENTEBTAINED
```

Figure 4 - The Incorrect Initial Structure for Sentence (4. 1)

So IF has completed its job. It has found what it takes to be the correct meaning of the verb. Now the rest of the sentence must be handled. The second element of every top-level list in the p-parse is a flag which is initially NIL, rut which is turned on when that part of the sentence is considered tc be correctly handled. In our example, so far only two parts are so flagged: the first noun phrase: "the man", and the verb phrase. The function which takes care of the rest of the sentence siaply goes down the p-parse checking these flags. If it finds one which is NIL it works on that part of the sentence until it either succeeds, or fails -- causing back-up.

In our example, then, the first phrase it comes upen needing work is the prepositional phrase: "beside the mindow."

There is a structure in the system which associates each preposition with the cases it may flag. BESIDE flags the cases: LOCATION and DESCRIPTIVE.

A11 of the cases but DESCRIPIIVE are cases of the verb. DESCRIPTIVE is a special case which is used for preposition
phrases which modify nouns.
When the list of cases associated with a prepcsition is retrieved, there is a question as to which case to try first. For this there is a foregrounding routine. There are several criteria for foregrounding:

First of all, on the property list of each verb is kept a record of which prepositions flagged which cases in the previous sentences. The cases associated with the preposition in question (if there are any) are foregrounded, so they will $\mathrm{f} \in$ tried first (the most recent case first, etc.)

Secondly, if DESCRIPTIVE is one of the cases in the list of cases for this preposition, and if a noun phrase or a prepositional phrase immediately precedes the phrase in question, and if the noun in that noun fhrase or preposticnal phrase is not a proper noun, then DESCRIPTIVE is put at the front of the list, so it is tried first.

This seemingly obscure rule for foregrounding the DESCRIPTIVE case is just a heuristic. If the tests associated with each case are good enough, it makes no difference to the final outcome if the foregrounding is done or nct. In some instances, however, if the DescriptIve case is not tried first, it will never be tried. In cur example, for instance, it is the man who is beside the window (DESCBIPTIVE case); be dic not play the piano beside the window (LOCATION case). But it is perfectly feasible for him to have played it beside the window (if we know nothing about the location of the fianc.) So either of the cases will succeed. It is only the position of the prepositional phrase that indicates which case is correct.

Continuing with our example: the CESCRIPTIVF case is foregrounded, and so the descriptive case functicn, DESC, is invoked with the phrase "beside the window" as its argument. Since the descriptive case almost always involves a prepositional phrase modifying the noun phrase or prepositicnal phrase immediately before it, DESC first checks to see if "beside the window" is a possible descriptor of "the man."

Since we do not have a data base to check to see if there is a man beside a window, our check must be a general one. Most nouns have a size associated with thex under the indicator OBJ-SIZE. This is a very crude breakdown of objects into $\in l \in v \in n$ size categories. "The world" is size 10 and "a fin" is size 0 . (As has been pointed out by an esteemed colleague, these sizes should be able to be changed by classifiers, adjectives, or modifying phrases. A toy elephant is probably not the same size as an elephant. This feature is currently not implemented.) The check for "beside" is merely used to rule out things like "the pin beside Canada." Abstract nouns have nc size information, so sentences like "He had a thought beside the ocean" are not ambiguous. In any event, "beside the window" is found to be a likely modifier of "the man", so DESC succeeds.

Since "beside" is a locative type cf frefosition, DESC returns the structure:
( <-LOC- BESIDE (NP (N WINDOW (NUMBER SG) (<-DEFINATE-THE))))

A form is stacked which will put this structure intc the main sentence structure if the rest of the sentence can te
handled. Just where it is placed is determined $k y$ resc. Since the prepositional phrase modifies "the man", it will be fut in as follows:

```
N MAN
    NUMBER SG
    <-DEFINITE- THE
    <-LOC- BESIDE
        N WINDOW
            NOMBER SG
            <-DEFINITE- THE
```

Figure 5-The Structure for "the man beside the window"

So the prepostional phrase "beside the window" is flagged as completed, and the next unflagged phrase, "the piano", is picked up.

Here we run into problems. Where does "the piano" fit into the structure? What does it modify? What is its case? There are relatively few ways a noun phrase can be used at this point. It could be an example of the TIME case, as in "I came home this morning.", but "piano" fails the TIME-test. It could $t \in a$ classifier, but the phrase following it would have tc te a noun phrase for this to be the case. So we have a failure. Something has gone wrong. IF must have chosen the wrong meaning of the verb. So we back up.

All the parts of the sentence that are flagged as used are un-flagged, and we back up into $I F$ again. Here it is found that there are no meanings of the verb left to try. one cf the meanings that was rejected earlier must have been the correct one. So we fail out of $I F$ and get back into the top-lєvel back-
up mechanism.
There are two reasons we could have failed:

1) Either we did not look far enough back in cut attempt to resolve an anaphoric reference.
or
2) Our tests were too severe. (ie: the sfould-EE tests made us fail when they should not have.)

The anaphoric part of the system has not been explained yet, that will come later, but there were no proncuns in the sentence, so the first reason can be ruled out. In order to weaken the tests, a flag is set to shut cff the SHOULD-BE tests. That is, all SHOULD-BE tests will succeed in future.

So we enter IF once again.
We start as before, but this time the first invocation of AGENT will succeed, because the test

```
(AND (SHOULD-BE MUSICIAN) (MUST-EF HOMAN))
```

succeeds. So the structure it returns is put in theregister AG.

Then IF takes us into the second triple of parameters. Tbe form
is EVALed.
PatIENT is very similar to AGENT: it looks in the appropriate place in the sentence for the patient of the verb. It then applies its TEST to it. In an active sentence, such as our example, the candidate for PATIENT is the first ncun phrase after the verb. "The piano" is found. Since it passes the test
(MOST-BE MOSICAL-INSTROMENT)

PATIENT returns "the piano" as the patient of the sentence.
So again IF thinks it has found the correct meaning of the verb, and so it EVALs the BUILDQ asscciated with that meaning, and the following structure is built:

```
<==>
        N MAN
            NUMBER SG
            <-DEFINITE- THE
        PAST
        <-- DO
        <-CAUSE-
            <=#>
                N PIANO
                            NUMBER SG
                            <-DEFINITE- THE
                PAST
                <-- EMIT
                        NP
                N SOUND
```

Figure 6 - The Correct Initial Structure for Sentence (4.1)
(An aside: I do not intend to defend the structures that my system returns. They are vaguely like the structures that Schank's system returns, as illustrated in Chafter 1, but are
more or less arbitrary. If the user does not like them they are easy to change.)

Once again we must try to clean up the unflagged parts of the sentence. The first one again is "beside the window", and exactly the same thing is done that was done before: it is decided that "beside the window" is a lccative descriftor of "the man", and this decision is stacked for later action.

The only other part of the sentence tc be handed is "for Mary." As with "beside", the cases associated with "for" are returned from the CaSE-TABLE. They are: DURATION, BENEFICIARY, EXCHANGE, and IND-SUBJ. (IND-SUBJ has not been implemented yet.) Assuming that there have been nc relevant previous sentences, the foregrounding of cases will have no effect on this ordering.

The DURATION case is tried first. CURATION is a particularly simple case. Basically it checks tc see that the noun phrase in the prepositional phrase has the property TIME under the flag N-PROP. "Mary" fails this test, sc DORATICN is rejected as being the correct case.

The next case is beneficIary. The cnly test for this case is that the noun phrase be animate. "Mary" passed this test since it has the SUPERSET WOMAN and WOMAN has the N-FROP ANIMATE. SO BENEFICIARY succeeds and returns:

$$
\text { ( }<- \text { BENEFICIARY- (NPR MARY)) }
$$

Unlike "beside the window", this phrase is a case of the verb. All cases of the verb (but agent and fatifnt) are considered to
be essentially parallel uith respect to the verb, sc they are put into the structure at the same level: that of the verb syinbol "<--", and their crder is independent. So a form is stacked to put the above structure intc the wain sentence structure in the correct location.

Next the p-parse is checked for more unused fhrases. None are found, so we are done.

The two forms are put into the structure, and it is returned as the "meaning" of the sentence:

```
<==>
N MAN
                                    NUMBER SG
        <-DEFINITE- THE
        <-LOC- BESIDE
            N WINDOW
                            NUMBER SG
                            <-DEFINITE-THE
PAST
<--DO
<-CAUSE-
        <==>
            N PIANO
                    NUMBER SG
                    <-DEPINITE- THE
            PAST
            <-- EMIT
                    NP
                    N SOUND
<-BENEFICIARY-
            NPR MARY
```

                    Figure 7 - The Final Structure for Sentence (4.1)
    
## CHAPTEF 5

-L. Cchen

## SOME DETAILS

## SECTION 5.1 Anaphoric References

Perhaps it is not the function of a parser to resclve anaphoric references, but this system was constructed to be a front end to a larger system which would require references to be resolved, so a mechanism for resolving them was put in. As has been said before, this system is not designed with any particular domain in mind, so no data base is keft. The resolution of anaphoric references, therefore, must defend solely on the previous sentences. The anaphoric routines will have to be changed to work in a larger system which maintains some kind of global structure describing what has gene cn sofar and how it fits into the world knowledge that the system has. The anaphoric capabilities were put intc this system because, if
a reference is unresolved the system cften cannct tell what case it is. They were also put in to illustrate how well such a mechanism fits into the case paradigm.

Only the tasic idea of how anaphoric references are resolved will be given here, along with examples illustrating the range of the system's capabilities.

When a pronoun is found in the sentence (in the case analysis, not the $A T N$ parse), it triggers a call to the function ANAPHORIC. ANAPHORIC takes four arguments:

1. A list of cases to lock fcr.
2. A test that the referent must pass.
3. A number indicating how far back in the histcry tc look.
4. The pronoun referenced.

The search is breadth first, in that the program tries very hard to find the referent in the earliest possible sentence. The test is an arbitrary form. SHCOID-EE and MUST-EF $\in l \in \mathbb{I} \in \operatorname{li}_{\mathrm{n}} \mathrm{s}$ of the test are shat off on failure as they are in the rest of the back-up procedure. (See Chapter 4)

Say, for instance, that the system is given the sentence:
(5.1) He played the piano.

The call to AGENT would be the form:
(AGENT (AND (SHOULD-BE MOSICIAN) (MUST-BE HUMAN)))

Since the obvious candidate for the agent is a proncun,

ANAPHORIC would be invoked. Its TEST would be:
(AND (SHOULD-BE MUSICIAN) (MUST-EE RUMAN))

So ANAPHORIC $u o u l d$ look back through the parses and pparses of the recent sentences which are kept as glcal variables, looking for a noun phrase that will pass this test. As it becomes more and more desperate it will make the test less strict. Since "he" is the proncun, aNAPHORIC is smart enough to insist that the referent be male and animate.

Most, pronoun references within a sentence itself can also be resolved. For instance:
(5.2) Fred went to Londcn so he cculd visit the queen. (5.3) Jack took you up in his airplane.

References to events and places can also be handed:
(5.4) It was unfortunate that the children were killed.
(5.5) I went to France. Pred lives there.

The resolution of locational references ("here" and "there") is a hard problem. By treating "there" as a pronoun whosereferent must be a location, "there" is handled fairly well by the system. "Here" is a much more difficult prorlem, since its resolution is highly context dependant, and is hardly addressed at all.

There is still one problem with references within a
sentence, and that is that if the referent of a froncun in the main clause is in a subordinate clause, then it will not be resolved. For instance, in the sentence:
(5.6) While he walked home, Fred was mugged.
"Fred" is not even considered as a candidate for "he". It is a simple extension to put this in (ANAPHORIC just has to lock into subordinate clauses), but it has just not been done yet. More difficult problems are illustrated by sentence (5.7).
(5.7) Mary was aboard the Titanic when she sank.

This sentence is ambiguous: Mary could have sunk in a swimming pool while she was on the ritanic, but this is frobably not the intended meaning. If "to sink" is defined with a test like
(SHOULD-BE BOAT)
then the system will pick up "Titanic" correctly. Its first choice as a candidate is "Mary", however, so if the test does not rule "Mary" out, the system will choose her as its initial guess.

This perhaps illustrates a fundamental problem with the system's anaphoric routines. The first candidate found which passes the test is chosen, rather than all of the candidates being locked at, and the most likely accepted.

SECTION 5.2: Particles

There are many verbs in English which, when used with a particle, take on a very different meaning.
(5.6) Pick a girl.
(5.7) Pick up a girl.
(5.8) Pick a girl up.
(5.9) Pick out a girl.

The policy with particles in this system is to create a new verb by tacking the particle onto the end of the infinitiveform of the verb. So (5.7) and (5.8) both become
(5.10) Pick-up a girl.

This conjuction takes place in the ATN. Each vert that takes one or more particles has a list of particles on its property list under the indicator EABTICLES. The verb "to look", for instance has (FOR AT LIKE). on its property list. (Look can take other particles: up, into, etc. but they are not currently handled by the system.) In the dicticnary explicit entries are made for the verbs LOCK-FCR, LOCK-AT, and LOOK-LIKE as well as Look. This usually works well, but it sometimes leads to problems. Consider the sentence

> (5. 11) John looked for Mary.

This sentence is ambiguous. "Mary" could be the patient of the.
verb "look-for", or the patient could be unspecified, and "for Mary" be the beneficiary case, or even the exchange case. The problem is that the atn is purely syntactic, and it is not fart of the back-up mechanism, so the system will always choose the "look-for" meaning.

Let me re-iterate that the system usually works correctly on particles, but in a more competent system the decision about conjoining particles to verbs will have to be put off until the semantics are at work.

SECTION 5.3: E[gative yerbs

There are problems with many of the cases in this system. In particular, the agent case is not properly defined.
(5.12) The door opened.
(5.13) The key opened the door.
(5.14) He opened the door with the key.
(5.15) The key opened.

If AGENT were called on sentence (5.12) it would return "the door" as the agent, whereas the agent is actually unspecified, and "the door" is the patient. Similarily, it would choose "the key" as the agent in (5.13). There is a whole set of verbs that behave like open. They are described in SECTION 1.2.' Simmons calls them ergative verbs. This system handles them specially.

Basically, a routine, ERGATIVE, was written which uses AGENT as a routine for returning the first noun phrase of the sentence. By checking to see if it is animate ERGATIDE can tell if it is the agent as in (5.14) or the patient or instrument. If it is the agent the sentence offers no problems in this regard. If. it is not the agent, then the system can $i \in c i d \in$ between the instrument case and the patient by checking to see if there is a patient following the verb. . Thus the system would interpret "the key" in sentence (5.15) as the fatient. for more details look at the dictionary entry for "to open" or "to rreak" in APPENDIX IV and the ERGATIVE routine in APPENDIX $V$.

SECTION 5. 4 : Some Obvious Extensions
The purpose of this thesis was tc implement a fairly large case system, and to explore the use of case and the interaction between case, syntax, and semantics. In the time allotted for this work, then, the main concentration was on cases. Thus some fairly large gaps were left in parts of the system. It can cnly handle declarative sentences, for instance. This is nct because it would be incapable of handling questions and imperatives, but just because there were other things that were more challenging. Adding the ability to parse these other types of sentences whld basically just involve extending the arn tc transform them into declarative sentences with the appropriate flags indicating type, etc. There are lots of aTN's arcund which do this fairly well.

Harder questions wich were not addressed are those of conjunction, ellipses, and negation. Again, there are some atns which do mediocre jobs in these areas, but $I$ dc nct advocate pushing these difficult questions into that supposedly simple and fast portion of the system. It is possible that negation and conjuction could be put into the $A T N$, and still have a fast system if the arn just kept them as separate entities in its initial parse. That is. if it did not attempt to say what was being negated or conjoined, but left these decisions to the routines using case and semantics.

## CHAFTER 6

# Some women wait for Jesus sore women wait for Cain so $I$ hang upon my alter and hoist $\mathbb{M} y$ axe again 

-L. Cchen

## CONCLUSION

A sentence parser is a very small part of what is needed to have machine intelligence. Among a vast number of other things, the structures returned by a parser must be incorporated into a global structure which represents at least the information conveyed in the previous utterances, and some relevant world knowledge.

This thesis was not an attempt to design cr build such a global structure, but thoughts in this direction are certainly relevant to the extension of this type of system. Also rele vant is the question of the usefulness of case in such a structure.

It is clear that we want wore than a list of case parses in a global structure. Schank is almost certainly on the right track with his conceptual dependency networks. Much of what we convey in an utterance, or in a series of utterances is $n \in v \in r$ actually stated. Much is implied or inferred by the listener, and if a computer is to have any competence with language it must be able to determine these implicaticns and inferences, and to make them explicit in its global structure. Some attempt has
been made in this system to make explicit some of the unstated information in the sentential parses.

What has been learned by the work on this system? The most glaring message is probatly that using even the most simple syntactic parser before using semantics leads to proklems. If I were to write this system again. I would nct use an ATN as a pre-parser. One of the problems that my use of the atw causes is illustrated in seCTION 5.2, where the parser is unable to undo an erroneous decision to classify a word as a particle, but more generally, $I$ do not believe that cne can decide syntactically how to break a sentence up into the correct components for a semantic analysis. This becomes more and more obvious as one pushes this system into more complex sentences involving nested relative and subordinate clauses.

I am not. sure that Schank's fourteen ACTS form a good $s \in t$ of verbal primitives: they were not intuitive enough for me when I started this project, but my experience with this system leads me to strongly support his intent, at least, of carefully la ying down a small set of primitives, and being very hesitant to change the set later.

No semantic primitives were set down at the outset of this project. New ones were merely created as they were needed. The set of cases was extended in a similar, though more controlled manner. Future work with the current system will probably be hampered by this unstructured approach. to these difficult problems. Ptolemaic astronomers have been scorned for their naivity when they added epicycles upon epicycles in their attempts to model the solar system. We shculd therefore be very
suspicious of a natural language system that dees the same thing with semantic primitives and cases.

We have seen that there are some problems with this system, both linguistic and computational, but $I$ feel that it has $m \in t$ all of its objectives. The system employs case to hande a wide range of English sentences. It has illustrated problems with a certain approach, and we have seen ways arcund these difficulties. Finally, this system lends support to those of us Who believe that case will prove to be a useful tcol in machine understanding of language.

It is your world.... It is your $f l e s h$ that $I$ wear

## APPENDIX I: Some Examples

The following is a sample run of the system. Fach parse is in two parts. First comes the ATN partial parse. This is printed out only to illustrate the notion of the partial parse. After that comes the final parse of the sentence. It alwas begins with the symbol $<==$.

```
(LETS-GO)
    HELLO. YOU ARE NOW IN CONVEESATIONAL MOLE.
    ANY LISP FORMS WILL BE EVALED IN THIS MODE.
    YOU MAY RETURN TO LISP BY ENTERIEG A #.
    IF YOU ENTER A 左 AS A WORD IN A SENTENCE, THAT SENTENCE

APEENDIX II: SOMe Non=examples

In CHAPTER 2 many examples are given of fhrases which fit into 盺 set of cases. There are, however, many which do not. Here are a few of them.

I know from her smile that tonight will be fine. The METHOD case expects a sentence after "from".

I listen all night for your step on the stair.
LISTEN-FOR is not defined in the system, although it could be.

Looking at the late late show through a
semi=precious stone.
There is no direction or aEdium case.
I walked through the morning.
This is not really the Path case, although that is what the system would call it.
-. Between the ocean and your open vein.
-. Between the hour and the age.
. . . Rusted from the elbow to the finger. The type of structure in these three examples is not defined to the syst $\in$ 㥸.

I met a woman long ago.
The TIME case will not accept this.
I am turning into gold.
TURN-INTO is not defined.
You held onto me like $I$ was a crucifix.
The LIKE case does not expect a sentence.
He looked once behind his shoulder.
This is another example of the non-existant DIRECTION case.

She died without a whisper.
The system does not know about "without". It is a difficult word.

AEPENDIX III: A Formal Description of what the System Returns.

Symbols in upper-case are terminal symbols. Symbols in lower case are non-terminal symbols. A vertical bar, "ן", means either, but not both, can be taken. A symbol in parenthesese, "(....)", is optional. A symbol in square brackets with an asterisk following it, "[...]*", may be repeated one or more times.

```

## ARPENDIX IV: The Dictionary

Below is a copy of the dictionary currently used by the system. Chapters 3 and 4 briefly refer to certain parts of word definitions, but it is appropriate to give a fuller description of what appears in the dictionry.

Each dictionary entry is of the form
(WORD I1 P1 I2 P2 ... Ii Pi)
where Pi is a property which is to be put on the property list of WORD under the indicator Ii. Different word types have different indicators on their property lists. If a word falls into more than one syntactic category it may have the properties of all of the categories. For instance "close" is a vert and an adjective, thus it would have the indicatcr $v$ and the indicator ADJ. The only types of word whose dictionary entries will be described in full here are the two complex.ones: nouns and verbs. If these are understood, the lesser word types will be easy to follow.

Nouns have the following properties:

N: This indicates that the WORD is a noun. The property under $N$ indicates how plurals are formed. For instance:
( $O X \mathrm{~N}$ IRR)
(OXEN N (OX (NUMBER PL)))
(FRED NPR NONE)
(WATER N MASS)

The entry for "ox" indicates that it forms its plural irregularily. The plural form must be in the dictionary as a separate word. NPR is a special case of $N$ indicating that the noun is a proper noun. NONE indicates that there is no plural form of the ncun. Mass nouns have the property MASS under N .
$N-P R O P:$ Under this indicator is a list of properties of the noun.
(BOY N S N-PROP (YOUNG))
indicates that a boy has the property young.

SUPERSET: The noun's super-sets are put in a list under this indicator:
(BOY N S N-PROP (YOUNG) SUPERSET (MAN))
(MAN N IRR N-PROP (MALE) SUPERSET (HUMAN))
(HUMAN N S N-PRCP (ANIMATE) SUPERSET (ANIMAL))
the $N$-PROP and SOPERSET properties form a network whereby BOY, for instance, will be found to be animate through the
above chain of SUPERSETS and N-PROPS. To avoid a lot of searching, redundant information is often put in:
(BOY S S-PBOP (HUMAN MALE YOUNG)
SUPERSET (MAN HUMAN)).

OBJ-SIZE: is the indicator whose property is a number from 0 10 giving a rough estimate of the size of an object. Some nouns such as Joy will not have this property.

NOM: This is used if a noun can have more than one number. For instance, the noun "paper" is defined as:
(PAPER N S N-PROP (INFLAMABLE LITERATURE) SUPERSET (OBJECT) OBJ-SIZE 1 NOM (MASS))

The property under NUM indicates that paper can $b \in$ a mass noun, as in "the room is full of paper."
"Football" has

NUM (MASS (SPORT GAME))
on its property list indicating that if football appears as a mass noun, it only has the $N-P R O P S$ SFORT and CAME frcm the whole set on its property list:

```
N-PROP (SPORT GAME CBJECT)
```

This is needed because the system only uses one set of properties to cover all of its meanings.

Verbs have the following indicators:

V: This is the verb indicator. Its property indicates how the first-person singular and the past tense are formed.

```
(KICR V S-ED)
(GIVE V IRR)
(GAVE V (GIVE. (TNS PAST)))
(GIVING V (GIVE (PART PREPART)))
(GIVES V (GIVE (TNS PRESENT)))
```

Irregular verbs have IRR as the property under v. All of the tenses of an irregular verb must be listed separately in the dictionary, giving the infinitive form of the verb and the tense or whatever of the form in questicn.

PREP-CASE: This is for the foregrounding routines. It is a list of lists. Each sub-list starts with a prepostion, which is followed by a variable number of cases. These cases are always tried first and in the order in which they appear when the prepostion is encountered in the sentence with that verb.

V-MEAN: The procedural definition of the verb is the property of

V-MEAN. CHAPTER 3 gives all of the details.
ro-comp: If the verb can take a to-complement. $T$ is under this indicator.

THAT-COMP: If the verb can take a that-complement, $T$ is under this indicator.

PARTICLES: If the verb takes one or more particles, they are listed here.

## AEPENDIX V: The Code

The code for this system is presented here in four parts. The first is the main part of the system: the case-analysis code. The routines are in alphabetic order.

The next part is the ATN grammar. This starts on page 129.
The third part is on page 137, and is just a few auxiliary routines.

Finaly is listed the $A T N$ parser which was written $k y$ Dr. Raymond Reiter at UBC.

```

[^0]:    1. For a detailed description of just what properties go with what word types see APPENDIX IV.
[^1]:    ${ }^{1}$ An example of a to-complement is: "Fred took the kook to ang $\underline{f}$ Maモy."
