THE FACULTY OF GRADUATE STUDIES
(Department of Chemistry)

We accept this thesis as conforming to the required standard

#### Abstract

Several new $\mathrm{Ru}(\mathrm{III})$ maltolato (ma) and ethylmaltolato (Ema) complexes have been synthesized, characterized, and tested for biological activity in vitro against MDA-MB-435S cells, a human breast cancer cell line. $\mathrm{Ru}(\mathrm{ma})_{3}(\mathbf{1})$ and $\mathrm{Ru}(\mathrm{Ema})_{3}$ (2) were studied in detail using a number of spectroscopic techniques. In particular, the solution ${ }^{1} H$ NMR spectra of these paramagnetic solids were investigated and, through the use of 

Maltol $(\mathrm{R}=\mathrm{Me})(\mathrm{Hma})$ and Ethylmaltol (HEma) ( $\mathrm{R}=\mathrm{Et}$ ) 

Metronidazole 

EF5

2D NMR techniques, structural information about the complexes was determined. These two complexes were then used to synthesize bis-imidazole complexes via removal of one ma or Ema ligand with triflic acid. Trans- $\left[\mathrm{Ru}(\mathrm{ma})_{2}(2 \mathrm{MeIm})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3} \quad(\mathbf{1 0})$, $-\left[\mathrm{Ru}(\mathrm{ma})_{2}(\mathrm{MeIm})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3} \cdot \mathrm{CH}_{2} \mathrm{Cl}_{2}$ (8), and $\left.-\left[\mathrm{Ru}(\mathrm{Ema})_{2} \text { (metro) }\right)_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$ (11), where $2 \mathrm{MeIm}=2$-methylimidazole, $1 \mathrm{MeIm}=1$-methylimidazole, and metro $=$ metronidazole, were synthesized and characterized by X-ray crystallography, while trans$\left.\left[\mathrm{Ru}(\mathrm{ma})_{2} \text { (metro) }\right)_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}(4)$ was also synthesized and subsequently characterized by X ray crystallography by another member of our group. Comparison of the ${ }^{1} \mathrm{H}$ NMR data of 8, 10, and $\mathbf{1 1}$ with those for the analogous complexes $\left[\mathrm{Ru}(\mathrm{ma})_{2}(4 \mathrm{MeIm})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3} \cdot \mathrm{CH}_{2} \mathrm{Cl}_{2} \quad$ (6), $\quad\left[\mathrm{Ru}(\mathrm{Ema})_{2}(4 \mathrm{MeIm})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3} \quad$ (12), and $\left[\mathrm{Ru}(\mathrm{Ema})_{2}(2 \mathrm{MeIm})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}(\mathbf{1 3})$, where $4 \mathrm{MeIm}=4$-methylimidazole, implies that these last three complexes also have trans-configurations. By a similar comparison, $\left[\mathrm{Ru}(\mathrm{ma})_{2}(\mathrm{Im})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}(7)$, where $\mathrm{Im}=$ imidazole, was found to be a mixture of cis- and trans-isomers that could not be separated.

$10(\mathrm{R}=\mathrm{Me}), 13(\mathrm{R}=\mathrm{Et})$

$6(\mathrm{R}=\mathrm{Me}), 12(\mathrm{R}=\mathrm{Et})$

8

The ma and Ema complexes were then tested in vitro using a so-called MTT assay against human breast cancer cells to evaluate their antiproliferatory activity. This assay determines cell viability as a measure of the cell's ability to reduce the yellow MTT (3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide) to the purple formazan in the mitochondria. Complexes containing Ema exhibited lower $\mathrm{IC}_{50}$ values (complex concentration at which cell proliferation has been reduced by $50 \%$ after 3 days), than the corresponding ma complexes, and 13 exhibited the lowest value of 500 nM , compared to that for cisplatin $\left(\mathrm{IC}_{50}=40 \mu \mathrm{M}\right)$. Ru-uptake data showed that Ema complexes were taken into Chinese Hamster Ovarian (CHO) cells at levels 4-5 times greater than those for corresponding ma complexes. No significant difference in Ru-uptake was observed between ma complexes with different imidazole ligands when these lacked a nitro group. $\left[\mathrm{Ru}(\mathrm{ma})_{2}(\mathrm{EF} 5)_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3} \cdot \mathrm{EtOH}$ (14), where EF5 $=2$-(2-nitro-1-H-imidazol-1-yl)-N-(2,2,3,3,3-pentafluoropropyl)acetamide, exhibited the highest Ru-uptake of the complexes tested, and was the only complex to exhibit DNA-binding in CHO cells over a 3 h incubation period, although it exhibited very low activity in the MTT assay $\left(\mathrm{IC}_{50}\right.$ value $>500 \mu \mathrm{M})$.

Day 1 - Plate cells

Day 5 - Read plate

Outline for the MTT assay

Complexes containing the bidentate ligands 4,4'-biimidazole (biim) and 2,2'-dimethyl-4,4'-biimidazole ( $\mathrm{Me}_{2}$ biim) were also synthesized, characterized and tested by the MTT assay. The $\mathrm{Ru}($ III $)$ complexes $\left[\mathrm{Ru}(\mathrm{ma})_{2}(\mathrm{~L})\right] \mathrm{CF}_{3} \mathrm{SO}_{3} \cdot 2 \mathrm{H}_{2} \mathrm{O}$, where $\mathrm{L}=\operatorname{biim}$ (24) or $\mathrm{Me}_{2}$ biim (25), were synthesized from 1. The $\mathrm{Ru}(\mathrm{II})$ complexes $\left[\mathrm{Ru}(\mathrm{L})_{3}\right]\left[\mathrm{CF}_{3} \mathrm{SO}_{3}\right]_{2}(\mathrm{~L}$ $=\operatorname{biim}$ (26) and $\mathrm{L}=\mathrm{Me}_{2} \operatorname{biim}(27)$ ) were synthesized from $\left[\mathrm{Ru}(\mathrm{DMF})_{6}\right]\left[\mathrm{CF}_{3} \mathrm{SO}_{3}\right]_{3}$, while the complexes $\mathrm{RuCl}_{2}(\mathrm{DMSO})_{2}(\mathrm{~L})\left(\mathrm{L}=\operatorname{biim}\right.$ (20) and $\mathrm{L}=\mathrm{Me}_{2} \mathrm{biim}$ (22)) and $\mathrm{Ru}_{2} \mathrm{Cl}_{4}(\mathrm{DMSO})_{4}(\mathrm{~L})\left(\mathrm{L}=\operatorname{biim}(21)\right.$ and $\mathrm{L}=\mathrm{Me}_{2}$ biim (23)) were synthesized from cis$\mathrm{RuCl}_{2}$ (DMSO) $)_{4}$. 24-27 all exhibited significant activity in the MTT assay ( $\mathrm{IC}_{50}$ values $15-50 \mu \mathrm{M})$, but 20 and 22 were essentially inactive. The Ru-uptake values of $24-27$ in CHO cells were comparable to those observed for the Ru-ma bis-imidazole complexes (4, 6, 7, 8 and 10).

The new Ru complexes $\left[\mathrm{Ru}_{2}(\text { pic })_{4}(\mathrm{EtOH}) \mathrm{Cl}\right] \cdot \mathrm{H}_{2} \mathrm{O}$ (31) and $\mathrm{Ru}\left(\mathrm{Im}-\mathrm{CO}_{2}\right)(\mathrm{Im}-$ $\left.\mathrm{CO}_{2} \mathrm{H}\right)_{2} \mathrm{Cl}_{2} \cdot \mathrm{H}_{2} \mathrm{O} \cdot \mathrm{EtOH}(\mathbf{3 3})$, synthesized using the N -heterocyclic carboxylic acid ligands pyridine-2-carboxylic acid (Hpic) and imidazole-4-carboxylic acid $\left(\operatorname{Im}-\mathrm{CO}_{2} \mathrm{H}\right)$, were also tested using the MTT assay, but were considerably less active than either the biimidazole or bis-imidazole complexes ( $\mathrm{IC}_{50}$ values $=100$ and $400 \mu \mathrm{M}$ for 31 and 33 , respectively).

## Table of Contents

Abstract ..... ii

## List of Figures

Figure 1.1 Gradient of oxygen concentration in cancerous tumours (adapted fromref. 6). .......................................................................................................... 3
Figure 1.2 Molecular structures of metronidazole, EF5 and triF5 ..... 3
Figure 1.3 Proposed reduction pathway of nitroimidazoles (adapted from ref. 12). ..... 4
Figure 1.4 Molecular structures of $\mathrm{Pt}(\mathrm{II})$ anti-cancer complexes ..... 6
Figure 1.5 Pt-DNA adduct formed from a d(GpG) intrastrand cross-link ..... 7
Figure 1.6 Molecular structures of $\mathrm{Pt}(\mathrm{IV})$ anti-cancer complexes ..... 8
Figure 1.7 Molecular structures of Ru (III) anti-cancer complexes ..... 10
Figure 1.8 Molecular structure of NAMI-A. ..... 11
Figure 1.9 Molecular structure of $[\mathrm{RuCl}(p$-cymene $)(\mathrm{en})] \mathrm{PF}_{6}$. ..... 12
Figure 1.10 Molecular structure of $\mathrm{RuCl}\left(p\right.$-cymene)(BESE)] $\mathrm{PF}_{6}$ ..... 12
Figure 1.11 Molecular structure of $\left[\mathrm{Ru}(p\right.$-cymene $\left.) \mathrm{Cl}_{2}(\mathrm{pta})\right]$ ..... 13
Figure 1.12 Molecular structure of $\quad \alpha$-dichlorobis(2-phenylazopyridine)- ruthenium(II). ..... 13
Figure 1.13 Molecular structure of $\left[\mathrm{Ru}(\mathrm{phen})_{2} \mathrm{dppz}\right]\left(\mathrm{PF}_{6}\right)_{2}$. ..... 14
Figure 1.14 Molecular structures of maltol $(\mathrm{R}=\mathrm{Me})$ and ethylmaltol $(\mathrm{R}=\mathrm{Et})$ ..... 15
Figure 1.15 Molecular structures of tropolone and catechol. ..... 15
Figure 1.16 Molecular structure of $\mathrm{Ru}(\mathrm{ma})_{2}(\mathrm{DMSO})_{2}(\mathrm{R}=\mathrm{Me})$ and $\mathrm{Ru}(\mathrm{Ema})_{2^{-}}$ $(\mathrm{DMSO})_{2}(\mathrm{R}=\mathrm{Et})$ ..... 16
Figure 2.1 NMR set-up for performing the Evans method determination of $\mu_{\text {eff }}$ ..... 25
Figure 2.2 Cyclic Voltammetry cell used with Pt wire counter and workingelectrodes, and an Ag wire reference electrode28
Figure 2.3 Preparative TLC chamber with silica gel plate. ..... 30
Figure 3.1 Numbered molecular structures of imidazole and 3-nitro-1,2,4-triazole ..... 36
Figure 3.2 Molecular structure of $\mathrm{Ru}(\mathrm{ma})_{3}(\mathbf{1})$ ..... 36
Figure 3.3 ORTEP diagram of mer-Ru(ma) (1) with $33 \%$ probability thermal ellipsoids (see Appendix A1 for details) ..... 37
Figure 3.4 ${ }^{1} \mathrm{H}$ NMR spectrum ( $300 \mathrm{MHz}, 298 \mathrm{~K}$ ) of $\mathrm{Ru}(\mathrm{ma})_{3}(1)$ in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$. ..... 38

Figure 3.5 ${ }^{\mathrm{I}} \mathrm{H}-{ }^{-} \mathrm{H} \operatorname{COSY}$ spectrum ( $300 \mathrm{MHz}, 298 \mathrm{~K}$ ) of $\mathrm{Ru}(\mathrm{ma})_{3}(\mathbf{1})$ in $\mathrm{CD}_{2} \mathrm{Cl}_{2} \ldots . . .39$
Figure 3.6 $\quad{ }^{1} \mathrm{H}-{ }^{13} \mathrm{C}$ HMQC spectrum ( $300 \mathrm{MHz}, 298 \mathrm{~K}$ ) of $\mathrm{Ru}(\mathrm{ma})_{3}$ (1) in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$ with the ${ }^{13} \mathrm{C}$ spectrum on the left-hand side and the ${ }^{1} \mathrm{H}$ spectrum at the top. 40

Figure 3.7 Partial ${ }^{13} \mathrm{C}$ NMR spectrum of $\mathbf{1}(300 \mathrm{MHz}, 298 \mathrm{~K})$ in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$ generated as a positive projection of the $y$-axis from the ${ }^{1} \mathrm{H}-{ }^{13} \mathrm{C}$ HMQC spectrum of 1 . 41

Figure 3.8 Plot of the chemical shift (ppm) vs. $1 / \mathrm{T}\left(\mathrm{K}^{-1}\right)$ for the $\mathrm{H}(5)$ and $\mathrm{H}(6)$ protons on each ma ring of $\mathrm{Ru}(\mathrm{ma})_{3}(\mathbf{1})$, here labelled $\mathrm{H}(\mathrm{a})$-(f). .............. 42
Figure 3.9 Plot of the chemical shift (ppm) vs. $1 / \mathrm{T}\left(\mathrm{K}^{-1}\right)$ for the Me groups of

Figure 3.10 ${ }^{1} \mathrm{H}$ NMR spectrum of $\left.\mathrm{Ru}(E m a)\right)_{3}(\mathbf{2})(300 \mathrm{MHz}, 298 \mathrm{~K})$ in $\mathrm{CD}_{2} \mathrm{Cl}_{2} \ldots \ldots \ldots .$.
Figure $3.11{ }^{1} \mathrm{H}-{ }^{1} \mathrm{H}$ COSY spectrum of $2(300 \mathrm{MHz}, 298 \mathrm{~K})$ in $\mathrm{CD}_{2} \mathrm{Cl}_{2} \ldots \ldots \ldots \ldots \ldots \ldots \ldots . . . . . . .$.
Figure $3.12 \quad{ }^{1} \mathrm{H}-{ }^{13} \mathrm{C}$ HMQC spectrum ( $300 \mathrm{MHz}, 298 \mathrm{~K}$ ) of $\mathrm{Ru}(\mathrm{Ema})_{3}(2)$ in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$ with the ${ }^{13} \mathrm{C}$ spectrum on the left-hand side and the ${ }^{1} \mathrm{H}$ spectrum at the top 46
Figure 3.13 In situ formation of $\left[\mathrm{Ru}(\mathrm{ma})_{2}\left(\mathrm{CD}_{3} \mathrm{OD}\right)_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$ as shown by ${ }^{1} \mathrm{H}$ NMR spectroscopy, the broad downfield signal being characteristic of a transgeometry for the maltolato ligands (see text)48

Figure 3.14 Molecular structures for the trans-isomers of 4, 6-8 and 10.................. 49
Figure 3.15 Molecular structure of $\left[\mathrm{Ru}(\mathrm{ma})(1 \mathrm{MeIm})_{4}\right]\left[\mathrm{CF}_{3} \mathrm{SO}_{3}\right]_{2}(9)$........................ 50
Figure 3.16 ORTEP diagram of the cation of trans$\left[\mathrm{Ru}(\mathrm{ma})_{2}(1 \mathrm{MeIm})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3} \cdot \mathrm{CH}_{2} \mathrm{Cl}_{2}$ (8) with $50 \%$ probability thermal ellipsoids (see Appendix A2 for details). .................................................. 51
Figure 3.17 ORTEP diagram of the cation of trans-[Ru(ma) $\left.)_{2}(2 \mathrm{MeIm})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}(\mathbf{1 0})$ with $50 \%$ probability thermal ellipsoids (see Appendix A3 for details).. 52
Figure 3.18 Diagram depicting the potential steric interaction between an Im-Me group and the ma plane for $\mathbf{1 0}$. 53

Figure 3.19 Template with numbering scheme for crystal structure information displayed in Table 3.2.Figure 3.20 ORTEP diagram of the cation of trans- $\left[\mathrm{Ru}(\mathrm{Ema})_{2}(\text { metro })_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$ (11)with $50 \%$ probability thermal ellipsoids (see Appendix A4 for details). . 54
Figure 3.21 ${ }^{1} \mathrm{H}$ NMR spectrum of $\left[\mathrm{Ru}(\mathrm{ma})_{2}(1 \mathrm{MeIm})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}(\mathbf{8})$ in a) acetone- $d_{6}$ ( $300 \mathrm{MHz}, 298 \mathrm{~K}$ ) and b) $\mathrm{CDCl}_{3}(300 \mathrm{MHz}, 298 \mathrm{~K}$ ). .............................. 56
Figure 3.22 The effect of varying the temperature when reacting 1 with 1 MeIm. ..... 57
Figure 3.23 ${ }^{1} \mathrm{H}$ NMR spectrum ( $300 \mathrm{MHz}, 298 \mathrm{~K}$ ) of $\left[\mathrm{Ru}(\mathrm{ma})(1 \mathrm{MeIm})_{4}\right]\left[\mathrm{CF}_{3} \mathrm{SO}_{3}\right]_{2}$ (9)in acetone $-d_{6}$ showing the ma-Me at $\delta 81.6$ and $1 \mathrm{MeIm} \mathrm{H}(2)$ protons at $\delta$-19.4 and -24.0.58
Figure 3.24 ${ }^{1} \mathrm{H}$ NMR spectrum $(300 \mathrm{MHz}, 298 \mathrm{~K})$ of $\left[\mathrm{Ru}(\mathrm{ma})_{2}(2 \mathrm{MeIm})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}(\mathbf{1 0})$ in $\mathrm{CDCl}_{3}$. ..... 58
Figure 3.25 ${ }^{1} \mathrm{H}$ NMR spectra ( $300 \mathrm{MHz}, 298 \mathrm{~K}$ ) of a) $\left[\mathrm{Ru}(\mathrm{Ema})_{2}(2 \mathrm{MeIm})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$(13) in $\mathrm{CDCl}_{3}$ and b) $\left[\mathrm{Ru}(\mathrm{Ema})_{2}(4 \mathrm{MeIm})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}(\mathbf{1 2})$ in $\mathrm{CDCl3} \ldots \ldots \ldots \ldots . . .$.
Figure 3.26 Molecular structures of three compounds synthesized from F5. ..... 62
Figure 3.27 Synthesis of 2,2,3,3,3-pentrafluoropropylamine (F5) from 2,2,3,3,3- pentafluoroproprionic acid. ..... 63
Figure 3.28 Molecular structure of IMF10. ..... 64
Figure 3.29 ${ }^{19} \mathrm{~F}$ NMR spectrum ( $300 \mathrm{MHz}, 298 \mathrm{~K}$ ) of $\left[\mathrm{Ru}(\mathrm{ma})_{2}(\mathrm{EF} 5)_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3} \cdot \mathrm{EtOH}$(14). ........................................................................................................... 65
Figure 3.30 Cyclic voltammogram of $\left[\mathrm{Ru}(\text { metro })_{2}(\mathrm{ma})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3} \cdot(4)$ in MeCNcontaining ferrocene.67
Figure 4.1 Molecular structure of 2,2'-biimidazole. ..... 81
Figure 4.2 Synthesis for $\mathrm{H}_{2}$ biim and $\mathrm{H}_{2} \mathrm{Me}_{2}$ biim. ..... 82Figure 4.3 ORTEP diagram of 1,1'-bis(triphenylmethyl)-4,4'-biimidazole with $50 \%$probability thermal ellipsoids (see Appendix A5 for details). .................. 84
Figure 4.4 Molecular structure of 5,5'-diamino-3,3'-bi(1,2,4-triazole). ..... 86Figure $4.5 \quad{ }^{1} \mathrm{H}$ NMR spectra ( $300 \mathrm{MHz}, 298 \mathrm{~K}$ ) in $\mathrm{CD}_{3} \mathrm{OD}$ showing the imidazoleprotons of a) free $\mathrm{H}_{2}$ biim in $\mathrm{CD}_{3} \mathrm{OD}$, b) $1: 2 \mathrm{H}_{2}$ biim: $\mathrm{RuCl}_{2}(\mathrm{DMSO})_{4}$ after4 h at $65{ }^{\circ} \mathrm{C}$ in $\mathrm{CD}_{3} \mathrm{OD}$, and c) $1: 1 \mathrm{H}_{2}$ biim: $\mathrm{RuCl}_{2}(\mathrm{DMSO})_{4}$ after 4 h at 65${ }^{\circ} \mathrm{C}$ in $\mathrm{CD}_{3} \mathrm{OD}$............................................................................................ 88
Figure 4.6 Proposed solid state structure for $\mathrm{RuCl}_{2}(\mathrm{DMSO})_{2}$ (biim). ..... 88
Figure $4.7 \quad{ }^{1} \mathrm{H}-{ }^{1} \mathrm{H}$ COSY NMR spectrum $(300 \mathrm{MHz}, 298 \mathrm{~K})$ of 20 in $\mathrm{CD}_{3} \mathrm{OD}$. ..... 89
Figure 4.8 Mass spectrum of $\mathrm{RuCl}_{2}(\mathrm{DMSO})_{2}$ (biim) (20): the most intense group of signals is for ( $\mathrm{M}^{+}-\mathrm{Cl}$ - DMSO). ............................................................. 90
Figure 4.9 Structures (a) and (b) represent possible solution structures for 21, where all DMSO ligands are S-bound and $\mathrm{S}=\mathrm{CD}_{3} \mathrm{OD}$. ..................................... 92
Figure 4.10 ${ }^{1} \mathrm{H}$ NMR data ( $300 \mathrm{MHz}, 298 \mathrm{~K}$ ) for $\mathrm{Me}_{2}$ biim complexes. ...................... 93
$\begin{aligned} & \text { Figure 4.11 } \text { Mass spectrum for } \mathrm{Ru}_{2} \mathrm{Cl}_{4}(\mathrm{DMSO})_{4}\left(\mathrm{Me}_{2} \mathrm{biim}\right) \text { (23); the most intense } \\ & \text { group of signals is for }\left[\mathrm{M}^{+}-\mathrm{Cl}-3 \mathrm{DMSO}\right], \text { centred at } 551 \ldots . . . . . . . . . . . . . . . . . . ~ \\ & 94\end{aligned}$
Figure $4.12{ }^{1}$ H NMR spectra of 24 and 25. .................................................................. 96
Figure 4.13 Proposed structure for the cation of 24. ................................................... 96
Figure 4.14 Three possible structures for the cation of 25. .......................................... 97
Figure 4.15 Possible structure for a bis-biimidazole species, from reduction of the Ru
Figure 4.16 Molecular structure for 28........................................................................ 99
Figure 5.1 Binding modes of carboxylate groups with transition metal complexes; a) Monodentate, b) Chelating, and c) Bridging........................................... 110
Figure 5.2 Molecular structure of pyridine-2-carboxylic acid, Hpic....................... 111
Figure 5.3 ESI-MS spectrum (in MeOH ) of $\left[\mathrm{Ru}_{2}(\mathrm{pic})_{4}(\mathrm{EtOH}) \mathrm{Cl}\right] \cdot \mathrm{H}_{2} \mathrm{O}$ (31) clearly showing the $\left[\mathrm{M}^{+}\right.$- EtOH $]$fragment centered at 727. .............................. 112
Figure 5.4 Theoretical isotopic distribution for the $\left[\mathrm{M}^{+}\right]$peak of $\mathrm{Ru}\left(\mathrm{Im}-\mathrm{CO}_{2}\right)(\mathrm{Im}$ $\left.\mathrm{CO}_{2} \mathrm{H}\right)_{2} \mathrm{Cl}_{2} \cdot \mathrm{EtOH} \cdot \mathrm{H}_{2} \mathrm{O}\left(33\right.$, left) (Section 5.3), and for the $\left[\mathrm{M}^{+}-\mathrm{EtOH}\right]$ peak of $\left[\mathrm{Ru}_{2}(\mathrm{pic})_{4}(\mathrm{EtOH}) \mathrm{Cl}\right] \cdot \mathrm{H}_{2} \mathrm{O}(31$, right). ......................................... 113
Figure 5.5 ${ }^{1} \mathrm{H}$ NMR spectrum $(300 \mathrm{MHz}, 298 \mathrm{~K})$ of $\left[\mathrm{Ru}_{2}(\mathrm{pic})_{4}(\mathrm{EtOH}) \mathrm{Cl}\right] \cdot \mathrm{H}_{2} \mathrm{O}(\mathbf{3 1})$ in $\mathrm{D}_{2} \mathrm{O}$114
Figure 5.6 Proposed solid state structures for $\mathbf{3 1}$ where $\mathrm{N}-\mathrm{O} \equiv \mathrm{pic}^{-}$ ..... 115
Figure 5.7 Molecular structure of $\mathrm{Im}-\mathrm{CO}_{2} \mathrm{H}$. ..... 116
Figure 5.8 One possible isomer for the proposed structure for $\mathrm{Ru}\left(\mathrm{Im}-\mathrm{CO}_{2}\right)(\mathrm{Im}-$$\left.\mathrm{CO}_{2} \mathrm{H}\right)_{2} \mathrm{Cl}_{2} \cdot \mathrm{EtOH} \cdot \mathrm{H}_{2} \mathrm{O}(\mathbf{3 3})$ (solvent molecules not shown). .................. 117
Figure 5.9 Molecular structure of $\left[\mathrm{Ru}\left(\mathrm{PPh}_{3}\right)_{2}(\mathrm{~L}-\mathrm{H})_{2}\right]\left(\mathrm{L}-\mathrm{H}_{2}=\right.$ imidazole 4,5dicarboxylic acid).117
Figure 5.10 Mass spectrum of $\mathrm{Ru}\left(\mathrm{Im}-\mathrm{CO}_{2}\right)\left(\mathrm{Im}-\mathrm{CO}_{2} \mathrm{H}\right)_{2} \mathrm{Cl}_{2} \cdot \mathrm{EtOH} \cdot \mathrm{H}_{2} \mathrm{O}$, showing $\mathrm{M}^{+}$at 508. ..... 118
Figure 5.11 Molecular structure of HCANT ..... 119

Figure 6.11 Cell viability vs. concentration for $\left[\mathrm{Ru}(\mathrm{ma})_{2}\left(\mathrm{Me}_{2}\right.\right.$ biim $\left.)\right] \mathrm{CF}_{3} \mathrm{SO}_{3} \cdot 2 \mathrm{H}_{2} \mathrm{O}$ (25), with error bars representing $95 \%$ confidence limit ..... 147
Figure 6.12 Cell viability vs. concentration for $\left[\mathrm{Ru}(\mathrm{ma})_{2}(\mathrm{biim})\right] \mathrm{CF}_{3} \mathrm{SO}_{3} \cdot 2 \mathrm{H}_{2} \mathrm{O}$ (24), with error bars representing $95 \%$ confidence limit. ..... 147
Figure 6.13 Cell viability vs. concentration for $\left[\mathrm{Ru}\left(\mathrm{Me}_{2} \mathrm{biim}\right)_{3}\right]\left[\mathrm{CF}_{3} \mathrm{SO}_{3}\right]_{2}$ (27), with error bars representing $95 \%$ confidence limit. ..... 148
Figure 6.14 Cell viability vs. concentration for $\left[\mathrm{Ru}(\text { biim })_{3}\right]\left[\mathrm{CF}_{3} \mathrm{SO}_{3}\right]_{2}$ (26), with error bars representing 95\% confidence limit. ..... 149
Figure 6.15 Cell viability vs. concentration for $\left[\mathrm{Ru}_{2}(\mathrm{pic})_{4}(\mathrm{EtOH}) \mathrm{Cl}\right] \cdot \mathrm{H}_{2} \mathrm{O}$ (31), with error bars representing $95 \%$ confidence limit. ..... 150
Figure 7.1 CHO cells in $\alpha+/+$ medium ( $\sim 10^{6}$ cells $/ \mathrm{mL}$ ) ..... 156

Figure 7.2 Conical tube set-up used for CHO experiments (gas =air or $\mathrm{N}_{2}$ )........... 157
Figure 7.3 Colony of CHO cells after 7 days, following staining with methylene blue. 158

Figure 7.4 Structure of the indocarbocyanine fluorescent dye, Cy 3 , used to label the ELK3-51 MoAb. 161
Figure 7.5 Large cell colony formations resulting from clumped cells (A and B) compared with a colony grown from a single cell over the same time period, C. 163
Figure 7.6 Median fluorescence intensity of CHO cells incubated with EF5 or triF5 under $\mathrm{N}_{2}$ or air and then treated with the ELK3-51/Cy3 antibody.......... 169
Figure 7.7 Molecular structure of L-cysteine. .......................................................... 170

## List of Tables

Table 3.1 Variable temperature chemical shifts of $\mathrm{Ru}(\mathrm{ma})_{3}(300 \mathrm{MHz})$ in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$including values at $\mathrm{T}=\infty$, as determined by linear regression. ................ 42
Table 3.2 Selected X-ray data from bis-imidazole derivative structures. ..... 53
Table 3.3 ${ }^{1} \mathrm{H}$ NMR data of $\mathrm{Ru}(\mathrm{III})$ maltolato-imidazole complexes in $\mathrm{CDCl}_{3}$ at r.t. ..... 55
Table 3.4 ${ }^{1}$ H NMR data for the Ema-Im complexes 12 and 13, compared with those for the ma-Im complexes $\mathbf{6}$ and $\mathbf{1 0}$ ..... 60
Table 3.5 $\mathrm{Ru}($ III $/ \mathrm{II}$ ) reduction potentials of ma and Ema-containing complexes. ..... 66
Table 4.1 $\mathrm{Ru}(\amalg / \amalg)$ reduction potentials for the biimidazole complexes 24 and $\mathbf{2 5}$, compared with those for 7 and $\mathbf{1 0}$. ..... 97
Table 5.1 Selected IR spectral data for Ru carboxylate complexes. ..... 113
Table 6.1 Dilution table for the addition of complexes using a 4 mM stock solution. ..... 136
Table 6.2 $\mathrm{IC}_{50}$ values for the ligand precursors against MDA-MB-435S cells in L-15 medium after incubation at $37^{\circ} \mathrm{C}$ for 69 h . ..... 138
Table 6.3 $\quad \mathrm{IC}_{50}$ values for Ru-maltolato complexes against MDA-MB-435S cells inL-15 medium and against MDA435/LCC6-WT cells in DMEM after
Table 6.4 $\mathrm{IC}_{50}$ values for cisplatin, and three Ru complexes against MDA-MB-435S cells in L-15 medium after incubation at $37^{\circ} \mathrm{C}$ for 69 h . ..... 143
Table 6.5 $\quad \mathrm{IC}_{50}$ values for ethylmaltolato complexes against MDA-MB-435S cells in L-15 medium after incubation at $37^{\circ} \mathrm{C}$ for 69 h . ..... 143
Table 6.6 $\quad \mathrm{IC}_{50}$ values for biim and $\mathrm{Me}_{2}$ biim complexes against MDA-MB-435S cells in L-15 medium after incubation at $37^{\circ} \mathrm{C}$ for 69 h ; data for new Ru complexes containing picolinic acid (Hpic) or imidazole-4-carboxylic acid ( $\mathrm{Im}-\mathrm{CO}_{2} \mathrm{H}$ ) against the same cell line under the same conditions are also shown ..... 146

Table 7.1 Plating efficiency of CHO cells after a 3 h incubation period under both aerobic and anaerobic conditions with several $\mathrm{Ru}(\mathrm{mI})$ complexes at 100

Table 7.2 Uptake of Ru by CHO cells after a 3 h incubation period under both aerobic and anaerobic conditions with several Ru complexes at $100 \mu \mathrm{M} . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . ~ 166 ~$

Table 7.3 Amount of Ru associated with DNA isolated from CHO cells after a 3 h incubation period under both aerobic and anaerobic conditions with several $\mathrm{Ru}(\mathrm{III})$ complexes at $100 \mu \mathrm{M}$. 168

## List of Symbols and Abbreviations

| acac | acetylacetonate |
| :--- | :--- |
| Anal. | analysis |
| Ar | argon, or aryl |
| atm | atmosphere |
| biim | $4,4^{\prime}$-biimidazole |
| br | broad |
| Calcd | calculated |
| cat. | catalyst |
| CHO | Chinese Hamster Ovarian (cell line) |
| COSY | homonuclear correlation spectroscopy (NMR) |
| cymene | isopropyltoluene |
| d | doublet, deoxy |
| dd | doubly distilled |
| DMEM | Dubelco's modified essential medium |
| DMSO | S-bound DMSO ligand |
| DMSO | O-bound DMSO ligand |
| e | electron |
| E $_{1 / 2}$ | electrochemical half-wave potential |
| EDTA | ethylenediaminetetraacetato |
| EF5 | 2 -(2-nitro-1-H-imidazol-1-yl)-N-(2,2,3,3,3-pentafluoropropyl) acetamide |
| Ema | ethylmaltolato, 2-ethyl-3-hydroxy-4-pyronate |
| equiv. | equivalent(s) |
| ESI | electrospray ionization |
| FBS | fetal bovine serum |
| FeCp | ferrocene |
| FeCp* | bis(pentamethylcyclopentadienyl)iron(II) |
| G | guanosine |
| $\mathrm{H}_{2}$ biim | 4,4 '-biimidazolium trifluoroacetate |
| $\mathrm{H}_{2} \mathrm{Me}_{2}$ biim | $2,2^{\prime}$-dimethyl-4,4'-biimidazolium trifluoroacetate |

| HCANT | 3-nitro-1,2,4-triazole-5-carboxylic acid |
| :---: | :---: |
| HMepyr | 3-hydroxy-1,2-dimethyl-4-pyridone |
| HMQC | heteronuclear multiple quantum coherence |
| Hpic | pyridine-2-carboxylic acid, picolinic acid |
| $\mathrm{IC}_{50}$ | concentration at which $50 \%$ inhibition of cell proliferation is observed |
| Im | imidazole |
| Im- $\mathrm{CO}_{2} \mathrm{H}$ | imidazole-4-carboxylic acid |
| K | Kelvin (T) |
| LR | low resolution |
| LSIMS | liquid secondary ion mass spectrometry |
| m | multiplet, or medium intensity or milli |
| M | molar ( $\mathrm{mol} \mathrm{L}^{-1}$ ) |
| ma | maltolato, 3-hydroxy-2-methyl-4-pyronate |
| $\mathrm{Me}_{2} \mathrm{biim}$ | 2,2'-dimethyl-4,4'-biimidazole |
| 1 MeIm | 1-methylimidazole |
| 2 MeIm | 2-methylimidazole |
| 4MeIm | 4(5)-methylimidazole |
| metro | metronidazole |
| MoAb | monoclonal antibody |
| mol | mole |
| MS | mass spectrometry |
| MTT | 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium |
| NMM | N -methylmorpholine |
| $2 \mathrm{NO}_{2} \mathrm{Im}$ | 2-nitroimidazole |
| $4 \mathrm{NO}_{2} \mathrm{Im}$ | 4-nitroimidazole |
| $3 \mathrm{NO}_{2}$ tri | 3-nitro-1,2,4-triazole |
| ORTEP | Oakridge Thermal Ellipsoid Program |
| p | phosphodiester linkage in a DNA backbone |
| PBS | phosphate-buffered saline solution |
| PE | plating efficiency |
| pF | paraformaldehyde |

| q | quartet |
| :--- | :--- |
| r.t. | room temperature |
| s | singlet |
| solv | solvent |
| T | Thymidine |
| TBAP | tetrabutylammonium hexafluorophosphate |
| TOF | time of flight |
| t | triplet |
| triF5 | 2 -(3-nitro-1-H-triazol-1-yl)-N-(2,2,3,3,3-pentafluoropropyl) acetamide <br> $\delta$ |
| $\lambda$ | chemical shift (ppm) |
| $\nu$ | wavelength (nm) |
| $\mu$ | wavenumber (cm ${ }^{-1}$ ) |
| $\eta$ | micro, or bridging coordination mode |
| [] | hapticity |
| $\}$ | concentration (mol L-1) |

## Key to Numbered Complexes

| 1 | $\mathrm{Ru}(\mathrm{ma})_{3}$ |
| :---: | :---: |
| 2 | $\mathrm{Ru}(\mathrm{Ema})_{3}$ |
| 3 | $\left[\mathrm{Ru}(\mathrm{ma})_{2}(\mathrm{EtOH})_{2}\right]^{2} \mathrm{CF}_{3} \mathrm{SO}_{3}$ |
| 4 | $\left[\mathrm{Ru}(\mathrm{ma})_{2}\right.$ (metro) $\left.{ }_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$ |
| 5 | $\left[\mathrm{Ru}(\mathrm{ma})_{2}(\right.$ metro $\left.)(\mathrm{EtOH})\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$ |
| 6 | $\left[\mathrm{Ru}(\mathrm{ma})_{2}(4 \mathrm{MeIm})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3} \cdot \mathrm{CH}_{2} \mathrm{Cl}_{2}$ |

## Acknowledgements

I would like to thank my supervisor Prof. Brian James for his help and guidance during the past five years, and for his encouragement in my development as a scientist. I would also like to thank Dr. Jörn Müller for allowing me the opportunity of coming to working with his research group for a year at the Technisches Universität (TU) in Berlin towards the completion of my degree here at UBC.

I thank the remaining group members, Maria, Julio and Paolo, as well as the many past members I have had the honour of working with, particularly Jo Ling, Craig, Nathan, Paul, Cristina, Adam, Ian, Matt, Guibin, Hossein, Erin and Marcio.

Without the assistance and helpful insight of my workmates in Berlin, the year I spent could not have been nearly as productive as it was, and so I would like to thank Mattel, Tews, Andy 'Mahlzeit' Hejl, Petra, Captain Schiller, and Speedy Kempf for all their help and the Polisches Frau for keeping me posted on travel deals and always reminding me that the end would eventually arrive.

I would also like to acknowledge the work of Dr. Brian Patrick of this department in solving the X-ray crystal structures in this thesis work. Thank you as well to Marietta and Liane for all of their help with the NMR spectroscopy work I performed. I thank too all the other members of the UBC Chemistry Department with whom I have had the pleasure of working.

Special thanks to the GSP: Gord, Pav, Joe and Pete for supporting me in all my endeavours and to Mark for nighttime blading and a friendship that has stood the test of time, some 22 odd years now.

Finally I would like to thank my family who have supported me in so many ways and have never failed to be a guiding light in my life. My parents who have always encouraged me in everything I have done and my brothers, Chris and Jon, who through friendly competition and brotherly understanding have helped me strive to do my best.

As a great French-Canadian once said...
"when you have snow and ice for 6 months of the year, you might as well skate."

## Chapter 1

## Introduction

### 1.1 Introduction

Although often thought of as a single condition, cancer actually consists of more than 100 diseases, all of which result from the uncontrolled growth of abnormal cells. Such cell growth is the result of genetic mutations that disrupt the normal function of the cell, and disable the cell's own internal repair pathways. This, in turn, leads to uncontrolled growth and spread of these abnormal cells. ${ }^{1}$ Cancer can be divided into five major subclasses; carcinomas (cancer of the epithelial cells), sarcomas (cancer of the muscle, bone, fat, or tendons), myelomas (cancer of the plasma cells of bone marrow), leukemias (cancer of the bone marrow), and lymphomas (cancer of the lymphatic system) with carcinomas accounting for $80-90 \%$ of total cases. The Canadian Cancer Society estimates that in 2003 almost 140,000 new cases of cancer will be diagnosed in Canada and over 67,000 Canadians will die from the disease. ${ }^{2}$ Based on current trends it is estimated that approximately $38 \%$ of men and $41 \%$ of women will be diagnosed with some form of cancer in their lifetime. ${ }^{2}$

Although the death rate of cancer patients has been steadily decreasing over the last ten years, there is still a great demand for new drug treatments, particularly in light of the fact that some cancer tumours develop resistance to drug treatment over time, while other types of cancer have only a very limited response to chemotherapy and can only prolong the life of the patient at best. ${ }^{3}$ One major goal in cancer research is to develop new drugs that can selectively target cancer tumours and trigger apoptosis, cell death, while exhibiting only limited side-effects to normal healthy tissue. Research directed at understanding tumour biology now makes it possible to specifically target tumour cells. ${ }^{4}$

Some of the differences between normal tissue and cancerous tumours result from the rapid growth and division often characteristic of malignant tumour cells. This can lead to poor vasculature forming around the tissue, generating a local region of low extra-
cellular pH and low oxygen concentration (hypoxia). ${ }^{5}$ Local regions of hypoxia have been exploited in the search of new cancer treatments (Section 1.6.1) and new cancer imaging agents (Section 1.2). The use of hypoxia selective imaging agents is important not only for the detection of tumours, but also to quantify the extent of hypoxia in a given tumour. The presence of hypoxic cells is a major limiting factor in the efficacy of radiotherapy and thus the diagnosis of such cells prior to prescribing a treatment is of the utmost importance. ${ }^{5}$

In this chapter the concept of hypoxia detection will be briefly introduced, followed by an introduction to the development of Pt anti-cancer compounds and a review of the rapidly evolving field of Ru anti-cancer compounds.

### 1.2 Nitroimidazoles and Hypoxia

Hypoxia is defined as a condition in which a tissue receives a reduced supply of oxygen. As stated in Section 1.1, hypoxic regions often occur in tumours due to poor vasculature resulting from rapid growth of the tumour. Although cells deprived of an adequate oxygen supply will ultimately die, a tumour at any given time, may possess a region of viable, hypoxic cells that will be resistant to radiation treatment. $\mathrm{O}_{2}$ diffuses from the capillaries through tissues, and in tumours containing hypoxic cells, a gradient of $\left[\mathrm{O}_{2}\right]$ is established with healthy cells nearest the capillary, then a region of viable hypoxic cells as the $\left[\mathrm{O}_{2}\right]$ decreases, with necrotic cells being those farthest from the capillary (Figure 1.1$)^{6}$. Regions of hypoxia in a tumour can cause problems in treatment, as hypoxic cells are considerably less responsive than normal tissue to radiation therapy. The effectiveness of radiation therapy is dependent on the partial pressure of oxygen inside the cell. This ratio of hypoxic to oxic doses of radiation required to produce the same biological effect is known as the oxygen enhancement ratio (OER). For sparsely ionizing radiation such as $\gamma$-rays or X-rays, OER values are typically between 2.5 and $3 .{ }^{6}$

Figure 1.1 Gradient of oxygen concentration in cancerous tumours (adapted from ref. 6).

Since the early 1970s, nitroimidazoles have been investigated as potential radiosensitizers. Radiosensitizers enhance the effectiveness of radiation therapy by binding to the damaged DNA caused by the free radicals that result from irradiation of the cell. In the case of nitroimidazoles, the nitro group is thought to react with damaged DNA under hypoxic conditions in a manner similar to that of oxygen under normal oxic conditions, making the DNA irreparable and thus leading to cell death. Metronidazole (Figure 1.2) was one of the first nitroimidazoles investigated as a potential radiosensitizer but was found to cause extreme gastrointestinal toxicity at biologically active doses. ${ }^{7}$ Since then, research has focused on the more electron affinic 2-nitroimdiazoles ${ }^{5}$ ( $\mathrm{E}_{1 / 2}$ values typically between -360 and -400 mV for $2 \mathrm{NO}_{2} \mathrm{Im}$ systems vs. -510 to -545 mV for $5 \mathrm{NO}_{2} \mathrm{Im}$ and -540 to -685 mV for $4 \mathrm{NO}_{2} \mathrm{Im}$ systems). ${ }^{8}$

Figure 1.2 Molecular structures of metronidazole, EF5 and triF5.

Some nitroimidazoles are also known to preferentially accumulate in hypoxic cells. 2-(2-Nitro-1-H-imidazol-1-yl)-N-(2,2,3,3,3-pentafluoropropyl)acetamide (EF5) (Figure 1.2) is currently undergoing clinical trials as a potential hypoxia imaging agent. ${ }^{9}$ Labelled with radioactive ${ }^{19} \mathrm{~F}$, this compound can be traced using positron emission topography (PET). ${ }^{10}$ EF5 accumulation can also be monitored using invasive techniques by detection of adducts formed with a fluorescent antibody (ELK3-51) that is specific for EF5. ${ }^{11}$

Both the detection and treatment of hypoxic cells by nitroimidazoles result from the reducibility of the nitro group under physiological conditions. The higher activity of 2-nitroimidazoles over other nitroimidazoles is likely a result of their more positive reduction potentials. It has been proposed that nitroreductase enzymes inside the cell carry out the reduction, and that the selectivity for hypoxic cells is a result of a lack of oxygen to carry out the reverse oxidation (Figure 1.3). ${ }^{12,13}$ The radical anion formed as a result of the one-electron reduction can then undergo further reductions or react with other components inside the cell. In the presence of oxygen, the radical anion is reoxidized rapidly to the nitro group, and the compound can then diffuse back out of the cell. ${ }^{13}$ The further reduction or other reactivity of the radical anion traps it inside the hypoxic cells and results in the accumulation of the reduced nitroimidazole species.

Figure 1.3 Proposed reduction pathway of nitroimidazoles (adapted from ref. 12).

### 1.3 In Vitro Bioassays

A detailed introduction to the bioassays used in this thesis work will be presented at the beginning of both Chapters 6 and 7. The MTT assay, used here as a preliminary screening assay for antiproliferatory activity and cytotoxicity of some newly synthesized Ru complexes, has been used similarly by several groups with other Ru complexes before proceeding with in vivo experiments. ${ }^{14-20}$ Ru-uptake and Ru-DNA binding assays are
also performed to quantify the amount of metal accumulated in cells or in DNA, respectively. ${ }^{21,22}$ These assays can be modified to place the cells under anaerobic conditions, and thus can be used to investigate the uptake of Ru under both normal and hypoxic conditions.

A monoclonal antibody specific for the side-chain of EF5 has been developed ${ }^{11}$ and is used in Chapter 7 to determine the hypoxic selectivity of 2-(3-nitro-1-H-triazol-1-yl)-N-(2,2,3,3,3-pentafluoropropyl)acetamide (triF5, Figure 1.2) for comparison with that of EF5 under the same conditions (medium, cell line, concentration).

### 1.4 Platinum Anti-Cancer Drugs

### 1.4.1 Cisplatin and Other Pt(II) Anti-Cancer Drugs

The first metal anti-cancer drug to be developed was cisplatin, discovered by Rosenberg et al. in 1965 after noting that the cell division of Escherichia coli bacteria in their reaction medium was being inhibited by an electrolysis product formed in situ from a Pt electrode. ${ }^{23,24}$ This product, identified as $\left[\mathrm{NH}_{4}\right]_{2}\left[\mathrm{PtCl}_{6}\right]$, was then converted to cis$\mathrm{PtCl}_{4}\left(\mathrm{NH}_{3}\right)_{2}$ via a photochemical process, while subsequent reduction gave the biologically active complex, cis- $\mathrm{PtCl}_{2}\left(\mathrm{NH}_{3}\right)_{2}$ (cisplatin, Figure 1.4). ${ }^{25}$ Cisplatin, the most active of a series of cis-amine Pt species against sarcoma 180 and leukemia L1210 tumour models in mice, entered clinical trials in 1971 and was approved for the treatment of testicular and ovarian cancer in 1978. ${ }^{26}$ Unfortunately, there are drawbacks to cisplatin therapy: action against a limited range of tumours, poor solubility (thus the drug requires intravenous administration), and several toxic side-effects. The high incidence of nausea, vomiting, neuropathy, ototoxicity and nephrotoxicity has led to the search for new metal complexes having similar activity but with fewer side-effects.

Carboplatin (Figure 1.4), a less toxic analogue of cisplatin, was introduced into clinical trials in 1981, and is the only other Pt complex that has received worldwide approval and regular clinical use. ${ }^{26}$ The major drawbacks of carboplatin therapy are that it is only applicable to the same narrow range of tumours as that of cisplatin and still must be administered intravenously.

Two other $\mathrm{Pt}(\mathrm{II})$-amine complexes have received limited approval for use in some countries. Oxaliplatin ((trans-L-diaminocyclohexane)oxalatoplatinum(II)) has been approved in France for the secondary treatment of metastatic colorectal cancer, while nedaplatin (cis-diammine-glycolato-O,O'-platinum(II)) has received approval in Japan for the treatment of some cancers. ${ }^{26}$

cisplatin

carboplatin

AMD473

Figure 1.4 Molecular structures of $\mathrm{Pt}(\mathrm{II})$ anti-cancer complexes.

More recently, the rational design of $\mathrm{Pt}(\mathrm{II})$ complexes with a greater steric bulk in the amine ligands in order to limit deactivation of the complex by glutathione has led to the development of AMD473, cis-(ammine)dichloro(2-methylpyridine)platinum(II) (Figure 1.4). AMD473 entered clinical trials after exhibiting improved activity over that of cisplatin against cisplatin-sensitive and -resistant cell lines; this complex is also sufficiently water-soluble that it can be administered orally, ${ }^{26}$ and is currently in Phase $\Pi$ clinical trials for treatment of hormone resistant prostate cancer (HRPC). ${ }^{27}$

The mechanism by which cisplatin arrests cell division is well understood. In aqueous solution, cisplatin undergoes chloride dissociation to give both mono- and diaqua species. In the presence of DNA, these species react with the $N(7)$ position on guanine bases, and give rise to either $\mathrm{d}(\mathrm{GpG})$ (Figure 1.5 ) or $\mathrm{d}(\mathrm{GpTpG})$ intrastrand crosslinks ( $\mathrm{d}=$ deoxy, $\mathrm{G}=$ guanosine, $\mathrm{p}=$ phosphodiester linkage and $\mathrm{T}=$ thymidine). ${ }^{28}$ The resulting intrastrand adduct can be removed and repaired by the cell; however, the intrastrand cross-link also results in a kink in the DNA that can then be recognized by damage-recognition proteins ${ }^{29}$ that may then block the repair enzymes from accessing the damaged DNA. ${ }^{30}$

Figure 1.5 Pt-DNA adduct formed from a $\mathrm{d}(\mathrm{GpG})$ intrastrand cross-link.

### 1.4.2 Platinum(IV) as a Pro-Drug

The anti-cancer activity of $\mathrm{Pt}(\mathrm{IV})$ complexes such as cis $-\mathrm{PtCl}_{4}\left(\mathrm{NH}_{3}\right)_{2}$ has been known since the discovery of cisplatin. ${ }^{23,25}$ Several $\operatorname{Pt}(\mathrm{IV})$ compounds have since been made in the hope that they might be activated by an in vivo reduction of the metal centre. At least three of these compounds (iproplatin, ${ }^{31}$ tetraplatin, ${ }^{32}$ and JM216, ${ }^{33-35}$ Figure 1.6) have entered clinical trials, but have ultimately failed to produce results better than those of cisplatin; trials with iproplatin and JM216 failed to produce significant in vivo effects, while treatment with tetraplatin gave acute toxic side-effects. Complexes that remain in the higher $\operatorname{Pt}(\mathrm{IV})$ oxidation state in the bloodstream have the potential advantage over $\mathrm{Pt}(\mathrm{II})$ complexes of undergoing fewer, unwanted side-reactions. This can result in fewer, toxic side-effects and thus a greater amount of the active drug arriving in the target cells. ${ }^{36}$ The higher lipophilicity of some Pt(IV) complexes can also lead to better cellular uptake. ${ }^{36}$

Iproplatin

Tetraplatin

JM216

Figure 1.6 Molecular structures of $\mathrm{Pt}(\mathrm{IV})$ anti-cancer complexes.

The rate of in situ reduction of $\mathrm{Pt}(\mathrm{IV})$ to $\mathrm{Pt}(\mathrm{II})$ varies greatly depending on the ligands bound to the metal, and the ease at which the metal centre is reduced may greatly influence its biological activity. ${ }^{36}$ Direct correlations between the activity of a complex and its $\operatorname{Pt}(\mathrm{IV} / \mathrm{II})$ reduction potential cannot always be made; the reduction potential of tetraplatin is about 300 mV more positive than that of JM216, yet both are highly active in vitro. ${ }^{36}$ It may be possible, though, to tune the reduction potential of complexes already known to be active, to try and slow the in vivo reduction so that the more active complex reaches and is taken up into the cells. ${ }^{36}$

### 1.5 Ruthenium Complexes and Their Potential as Anti-Cancer Drugs

Since the discovery of cisplatin, complexes with other transition metals have been investigated, and Ru complexes have emerged as strong candidates for potential therapeutic use. Some proposed mechanisms of action and potential anti-cancer drugs will be discussed in the following sections.

### 1.5.1 Activation by Reduction

$\mathrm{Ru}(I I \mathrm{I})$ complexes have been investigated as pro-drugs for potentially more active Ru (II) species, and a mechanism of activation by reduction may be the reason that several Ru (III) complexes have shown high levels of in vivo activity against various types of cancerous tumours. ${ }^{37}$ The concept is the same as the use of $\mathrm{Pt}(\mathrm{IV})$ as a pro-drug, to
deliver a greater percentage of active complex to the cancerous cells by starting with a less reactive species that then becomes activated by reduction in the hypoxic regions of tumours. $\mathrm{Ru}(I I)$ complexes are generally more substitutionally labile than those of $\mathrm{Ru}(\mathrm{II})^{37}$ and are thus more likely to lose ligands in vitro, opening coordination sites for DNA or other cellular targets.

### 1.5.2 cis- $\mathrm{RuCl}_{2}(\mathrm{DMSO})_{3}(\mathrm{DMSO})$

cis- $\mathrm{RuCl}_{2}(\mathrm{DMSO})_{3}(\mathrm{DMSO})$ (cis-DMSO) was first reported by our group in 1971. ${ }^{38}$ Studies suggesting that this complex could interact in vitro with DNA were reported in $1975{ }^{39}$ and this resulted in further studies comparing its antimutagenic properties with those of cisplatin. ${ }^{40}$ cis-DMSO, tested in vivo in mice implanted with Lewis lung carcinoma-, B16 melanoma-, and Mca mammary carcinoma tumour models, was as effective as cisplatin against primary tumour growth and lung metastases and significantly less toxic. ${ }^{40,41}$ Coluccia et al. have reported in vivo testing of cis-DMSO in mice bearing P388 and the cisplatin-resistant P388/DDP leukemia tumour models, and in the latter, cis-DMSO was more effective than cisplatin at reducing primary tumour growth. ${ }^{42}$
cis-DMSO likely acts via a DNA-binding mechanism, and several groups have reported its interactions with purines. ${ }^{43-45}$ Although the O-bound DMSO ligand of cisDMSO rapidly dissociates in aqueous solution, followed by the slow loss of one $\mathrm{Cl}^{-}$ ligand, ${ }^{46}$ Farrell and De Oliveira have reported a dicationic Ru-bis(adenine) complex in which the O-bound DMSO is retained and the two $\mathrm{Cl}^{-}$ligands are replaced by adenine. ${ }^{43}$

### 1.5.3 Ru-imidazole Complexes

Keppler et al. first reported on the synthesis and biological activity of imidazolium [trans-tetrachlorobis(imidazole)ruthenate(III)] (ICR) in 1987 (Figure 1.7). ${ }^{15}$ Since then, numerous studies on analogues of this complex using other N -heterocyclic ligands in place of imidazole have been reported. ${ }^{14,16-18}$ Preliminary studies of ICR against P388 leukemia-, Walker 256 carcinosarcoma-, and sarcoma 180 tumour-infected mice resulted in increased survival times (T/C values of up to 194 vs. $175 \%$ for cisplatin, ${ }^{15}$ where $T / C$ values are calculated as the survival time of mice treated with the
complex divided by the survival time of mice to which no complex was administered). The methylimidazole derivatives were less active than ICR against P388 leukemia (T/C values of $130-150 \%$ ), while (Htri) $\left[\right.$ trans $\left.-\mathrm{Ru}(\text { tri })_{2} \mathrm{Cl}_{4}\right]($ tri $=1,2,4$-triazole) also exhibited weaker activity $(\mathrm{T} / \mathrm{C}=138 \%) .{ }^{14}(\mathrm{HInd})\left[\right.$ trans $\left.-\mathrm{Ru}(\mathrm{Ind})_{2} \mathrm{Cl}_{4}\right]($ Ind $=$ indazole $)($ Figure 1.7) was as effective as ICR in reducing colorectal tumour growth (typically $50-80 \%$ reduction in growth) and was devoid of any side-effects at active dosages. ${ }^{41,47}$

Imidazolium pentachloro(imidazole)ruthenate(III) $\left((\mathrm{HIm})_{2}\left[\mathrm{Ru}(\mathrm{Im}) \mathrm{Cl}_{5}\right]\right)^{16}$ and the analogous triazole complex, $(\mathrm{Htri})_{2}\left[\mathrm{Ru}\left(\mathrm{tri}^{( }\right) \mathrm{Cl}_{5}\right],{ }^{14}$ exhibit survival rates in P388 tumourbearing mice that are lower than those for cisplatin and ICR (T/C $=150-162 \%$ for $(\mathrm{HIm})_{2}\left[\mathrm{Ru}(\mathrm{Im}) \mathrm{Cl}_{5}\right]^{16}$ and $150 \%$ for $\left.(\mathrm{Htri})_{2}\left[\mathrm{Ru}(\mathrm{tri}) \mathrm{Cl}_{5}\right]\right) .{ }^{14}$

Figure 1.7 Molecular structures of $\mathrm{Ru}(\mathrm{III})$ anti-cancer complexes.

### 1.5.3.1 NAMI and NAMI-A

$(\mathrm{HIm})\left[\right.$ trans $\left.-\mathrm{Ru}(\mathrm{Im})\left(\mathrm{DMS}_{\mathrm{O}}\right) \mathrm{Cl}_{4}\right]$ (NAMI-A) (Figure 1.8) exhibits an antimetastatic effect on several tumour models and is the only Ru complex to date to enter into clinical trials. ${ }^{41}$ In vivo studies show that both NAMI-A and NAMI ( $\mathrm{Na}[$ trans$\left.\mathrm{Ru}(\mathrm{Im})(\mathrm{DM} \underline{\mathrm{S}}) \mathrm{Cl}_{4}\right]$ ), like cisplatin, are capable of reducing primary tumour growth in Lewis lung carcinoma-, B16 melanoma-, Mca mammary carcinoma tumour-models by up to $40 \% .^{48,49}$ Unlike cisplatin, however, treatment with NAMI or NAMI-A also increased the life-span of the hosts, independent of the tumour model used, and reduced the
formation of lung metastases even when the inhibition of primary tumour growth was negligible. ${ }^{41}$ NAMI and NAMI-A are thought to arrest cells in the G2/M phase of the cell cycle, and do not appear to act via a DNA-binding mechanism, although they do bind DNA in vitro. ${ }^{50}$ The complexes may be activated by an in situ reduction to a $\mathrm{Ru}(\mathrm{II})$ species. ${ }^{51}$ The major advantage of NAMI-A over NAMI is that it is a more stable solid. ${ }^{51}$

Figure 1.8 Molecular structure of NAMI-A.

### 1.5.4 Ru-arene Complexes

Morris et al. have reported the synthesis and in vitro testing of $\mathrm{Ru}(\Pi)$-arene complexes against A2780 human ovarian cancer cells. ${ }^{19}$ Complexes such as $[\mathrm{RuX}(p-$ cymene)(en) $] \mathrm{PF}_{6}$, where $\mathrm{X}=\mathrm{Cl}$ or I (Figure 1.9), exhibited $\mathrm{IC}_{50}$ values ( 9 and $8 \mu \mathrm{M}$ for Cl and I , respectively) similar to that of carboplatin $(6 \mu \mathrm{M})$ against the same cell line, but more than an order of magnitude higher than that of cisplatin $(0.5 \mu \mathrm{M}) .{ }^{19}$ These complexes bind strongly to the guanine bases of DNA. ${ }^{19}$ It is thought that the arene group not only stabilizes the $\mathrm{Ru}(\mathrm{II})$ metal centre but may also help in cellular uptake by increasing the hydrophobicity of the complex. ${ }^{19}$ The range of Ru-arene complexes studied was then expanded by the same group who then reported that $[\mathrm{RuCl}-$ (tetrahydroanthracene)(en) $] \mathrm{PF}_{6}$ exhibited the lowest $\mathrm{IC}_{50}$ value, $0.5 \mu \mathrm{M}$, of a range of complexes tested, equal to that observed for cisplatin. ${ }^{52}$

Figure 1.9 Molecular structure of $\left[\mathrm{RuCl}(p\right.$-cymene) $(\mathrm{en})] \mathrm{PF}_{6}$.

Ru-arene complexes have also been synthesized in our group and tested for anticancer activity against MDA-MB-435S cells, a human breast cancer cell line. ${ }^{53}$ The complex, $\quad\left[\mathrm{RuCl}(p-c y m e n e)\left(\mathrm{BESE}^{2}\right)\right] \mathrm{PF}_{6}$ (Figure 1.10$)$, where $\mathrm{BESE}=1,2-$ bis(ethylsulfinyl)ethane, and the dimeric complex, $\left[\mathrm{RuCl}_{2}(p \text {-cymene })\right]_{2}(\mu$-BESE $)$, have been tested for activity using the MTT assay to determine their $\mathrm{IC}_{50}$ values. $\mathrm{RuCl}(p$ cymene $)($ BESE $)] \mathrm{PF}_{6}$ exhibited significant activity $\left(\mathrm{IC}_{50}=55 \mu \mathrm{M}\right)$ when compared with data for cisplatin $\left(\mathrm{IC}_{50}=10 \mu \mathrm{M}\right) .{ }^{53}$

Figure 1.10 Molecular structure of $\mathrm{RuCl}(p$-cymene) $(\mathrm{BESE})] \mathrm{PF}_{6}$.

A third group has reported on the pH dependent cytotoxicity of $\mathrm{Ru}(p$ cymene) $\mathrm{Cl}_{2}$ (pta) (Figure 1.11), where pta $=1,3,5$-triaza- 7 -phosphatricyclo[3.3.1.1]decane, which may also prove useful as an anti-cancer agent. ${ }^{54}$

Figure 1.11 Molecular structure of $\mathrm{Ru}(p-c y m e n e) \mathrm{Cl}_{2}(\mathrm{pta})$.

### 1.5.5 Ru-azopyridine Complexes

Velders et al. have reported on the activity of the so-called $\alpha$-isomer of dichlorobis(2-phenylazopyridine)ruthenium(II) (Figure 1.12) against 7 different tumour cell lines; ${ }^{20}$ the activity was invariably equal to or better than that of cisplatin, with $\mathrm{IC}_{50}$

Figure 1.12 Molecular structure of $\alpha$-dichlorobis(2-phenylazopyridine)ruthenium(II).
values being an order of magnitude lower than that of cisplatin in both the EVSA-T (a human breast cancer cell line) and M19 (a Chinese hamster ovarian cell line) cell lines. ${ }^{20}$ Two geometric isomers, the so-called $\beta$ - (containing cis-pyridine and cis- Cl ligands) and $\gamma$ - (containing cis-pyridine and trans-Cl) isomers were considerably less active. Believing that the $\alpha$-isomer acts in a manner similar to that of cisplatin by binding to the guanine bases of DNA, the same group later showed that this complex reacts with 9ethylguanine ${ }^{55}$ to form $\alpha$ - $\left[\mathrm{Ru}(2 \text {-phenylazopyridine })_{2}\right.$ (9-ethylguanine) $\left.\left(\mathrm{H}_{2} \mathrm{O}\right)\right]\left(\mathrm{PF}_{6}\right)_{2}$, with the guanine bound through the $\mathrm{N}(7)$ position; 3-methyladenine, correspondingly formed $\alpha-\left[\mathrm{Ru}(2 \text {-phenylazopyridine })_{2}(3\right.$-methyl-adenine $\left.)\right]\left(\mathrm{PF}_{6}\right)_{2}$, in which the adenine is chelated through the $N(6)$ and $N(7)$ positions. ${ }^{55}$ It was thought that such Ru-adducts might form in the presence of DNA and be responsible for the anti-tumour activity of $\alpha$-dichlorobis(2phenylazopyridine)ruthenium(II).

### 1.5.6 Ru Intercalators

Ru complexes with large conjugated ligands can also interact with the purine bases of DNA via $\pi$-stacking interactions. Such Ru intercalators are of particular interest in photodynamic therapy in which they can be activated to cause local damage to the surrounding DNA. ${ }^{37}$ Both enantiomers of $\left[\mathrm{Ru}(\mathrm{phen})_{2} \mathrm{dppz}\right]\left(\mathrm{PF}_{6}\right)_{2}$, where phen $=1,10$ phenanthroline and $\mathrm{dppz}=2,2^{\prime}$-dipyrido-3,3'-phenazine (Figure 1.13), exhibit a high affinity for DNA without loss of any chelating ligand. ${ }^{56}$

Figure 1.13 Molecular structure of $\left[\mathrm{Ru}(\mathrm{phen})_{2} \mathrm{dppz}\right]\left(\mathrm{PF}_{6}\right)_{2}$.

### 1.6 Maltolato (ma) Chemistry

Maltol (3-hydroxy-2-methyl-4-pyranone, Figure 1.14), is a water-soluble food additive with a $\mathrm{pK}_{\mathrm{a}}$ of 8.67 for the hydroxy group, ${ }^{57}$ the anionic form, maltolato (ma), can then chelate to transition metal centres. This is an attractive ligand to use in biological inorganic chemistry as complexes that contain one or more maltolato ligands are often water-soluble and the free ligand, if dissociated in vivo, is non-toxic. ${ }^{58}$

Figure 1.14 Molecular structures of maltol $(\mathrm{R}=\mathrm{Me})$ and ethylmaltol $(\mathrm{R}=\mathrm{Et})$.

### 1.6.1 Maltolato Complexes with Ru

$\mathrm{Ru}(\mathrm{ma})_{3}$, first reported by Griffith and Greaves in $1988,{ }^{59}$ was synthesized as part of a research project investigating the transition metal complexes of tropolone and catechol (Figure 1.15). Indeed, the assignment of the ${ }^{1} \mathrm{H}$ NMR spectrum of

tropolone

catechol

Figure 1.15 Molecular structures of tropolone and catechol.
$\mathrm{Ru}(\text { tropolonato })_{3}$, first discussed by Eaton et al., ${ }^{60}$ shows similarities to that of $\mathrm{Ru}(\mathrm{ma})_{3}$ which will be discussed in Chapter 3. El-Hendawy and El-Shahawi reported later the synthesis of another $\mathrm{Ru}(\mathrm{III})$ maltolato species, $\mathrm{RuCl}_{2}(\mathrm{ma})\left(\mathrm{PPh}_{3}\right)_{2},{ }^{61}$ while other groups have reported $\mathrm{Ru}(\mathrm{II})$ complexes containing one or more maltolato ligands. Fryzuk et al. have reported on cis-Ru(ma) $)_{2}\left(\mathrm{PPh}_{3}\right)_{2}$, cis-Ru(ma $)_{2}(\mathrm{DMSO})_{2}$, and cis-Ru(ma) $)_{2}(\mathrm{COD})_{2},{ }^{62}$ while Capper et al. have characterized $\mathrm{Ru}(\mathrm{mes}) \mathrm{Cl}(\mathrm{L})$ and $[\mathrm{Ru}(\mathrm{mes})(\mathrm{CO})(\mathrm{L})]\left(\mathrm{BF}_{4}\right)$ where $\mathrm{L}=$ maltolato (ma) or ethylmaltolato (Ema) and mes $=1,3,5$-trimethylbenzene. ${ }^{63}$

Our group has recently reported on the anti-cancer activity of Ru-maltolatosulfoxide complexes of the type $\mathrm{Ru}(\mathrm{L})_{2}(\mathrm{DMSO})_{2}$ where $\mathrm{L}=$ maltolato (ma) or ethylmaltolato (Ema) (Figure 1.16). ${ }^{64,65}$ These complexes were tested against the human breast cancer cell line MDA-MB-435S and exhibited $\mathrm{IC}_{50}$ values of $190(\mathrm{~L}=\mathrm{Ema}$ ) and $220 \mu \mathrm{M}(\mathrm{L}=\mathrm{ma})$, these data being taken from Wu's M.Sc. thesis. ${ }^{65}$ Replacement of the DMSO ligands by BESE (see Section 1.6.4) led to less active complexes. ${ }^{64,65}$ The higher stability of the chelated-BESE complexes in solution may limit the potential in vitro for the Ru to bind DNA or other cellular targets. ${ }^{64,65}$

Figure 1.16 Molecular structure of $\mathrm{Ru}(\mathrm{ma})_{2}(\mathrm{DMSO})_{2} \quad(\mathrm{R}=\mathrm{Me})$ and $\mathrm{Ru}(\mathrm{Ema})_{2}(\mathrm{DMSO})_{2}(\mathrm{R}=\mathrm{Et})$.

### 1.6.2 Maltolato Complexes with Other Transition Metals

$\mathrm{Fe}(\mathrm{ma})_{3}$ has been structurally characterized and proposed as a potential drug for iron-deficiency anaemia, ${ }^{66}$ while trivalent complexes of $\mathrm{Cr}, \mathrm{Mn}, \mathrm{Rh}, \mathrm{Ga}, \mathrm{In}, \mathrm{V}$ and Al
have also been reported. ${ }^{67,68} \mathrm{VO}(\mathrm{ma})_{2}$ and $\mathrm{VO}(\mathrm{Ema})_{2}$ are being studied as potential insulin mimetic drugs. ${ }^{69,70}$ Greaves and Griffith have also reported the syntheses of trans $-\mathrm{Os}(\mathrm{O})_{2}(\mathrm{ma})_{2}$, trans $-\mathrm{U}(\mathrm{O})_{2}(\mathrm{ma})_{2}$ and cis $-\mathrm{Mo}(\mathrm{O})_{2}(\mathrm{ma})_{2}{ }^{59} \mathrm{Sn}\left(\mathrm{ma}_{2} \mathrm{Cl}_{2}{ }^{71}\right.$ and $\mathrm{Sn}(\mathrm{ma})_{2}{ }^{72}$ have been synthesized, and other divalent maltolato complexes of $\mathrm{Co}, \mathrm{Ni}, \mathrm{Cu}$, and Zn have been reported. ${ }^{67}$ Numerous trivalent lanthanide complexes of the form $\mathrm{M}(\mathrm{ma})_{3} \cdot \mathrm{H}_{2} \mathrm{O}$ have also been synthesized $(M=\mathrm{La}, \mathrm{Pr}, \mathrm{Nd}, \mathrm{Sm}, \mathrm{Gd}, \mathrm{Dy}$, and Yb$) .{ }^{57}$

### 1.7 Goals of this Thesis

The goals at the onset of this thesis work were to synthesize and characterize new Ru-maltolato-imidazole and -nitroimidazoles complexes, and to investigate their toxicity, cellular uptake and interactions with DNA in cells using standard in vitro bioassays. Previous work in our group had shown that Ru-EF5 complexes could be used as potential radiosensitizers ${ }^{73}$ while other groups have shown that $\mathrm{Ru}(\mathrm{II})$ imidazole complexes may be good anti-metastasis drugs ${ }^{50}$ or intercalators. ${ }^{52}$ A 3-nitro-1,2,4-triazole analogue of EF5 was proposed as a possible new hypoxia selective agent, and was thus synthesized, characterized and tested; this compound was examined in vitro for hypoxia selective activity but proved to be not as effective as EF5. Of the Ru (III)-maltolato-imidazole complexes tested, several exhibited interesting biological activity, and as the biological testing proceeded, it became apparent that these complexes might also produce an antiproliferatory effect similar to that of NAMI-A, and thus the MTT assay was used as a general screening assay to probe complexes for anti-cancer activity.

The range of Ru complexes synthesized and characterized was then expanded to investigate complexes of several, bidentate ligands, especially imidazole-4-carboxylic acid, 4,4'-biimidazole and 2,2'-dimethyl-4,4'-biimidazole. Complexes of these ligands with $\mathrm{Ru}(\mathrm{ma})_{3}$ and several other Ru starting materials afforded several new complexes that were characterized and tested in preliminary in vitro bio-assays.

This thesis consists of 8 chapters, and appendices containing data for the 5 crystal structures presented. In Chapter 2, general experimental procedures and methods are discussed. The syntheses and characterization data of new Ru (III)-maltolato-imidazole
complexes are described in Chapter 3. The syntheses of 4,4'-biimidazole ligands, and the reactions of these ligands with both $\mathrm{Ru}(\mathrm{II})$ and $\mathrm{Ru}(\mathrm{III})$ precursors to afford new Ru biimidazole complexes, are described in Chapter 4. These ligands were designed initially to synthesize a bidentate biimidazole analog of EF5. Ultimately, the complexes with the biimidazole ligands were themselves found to be worthy of study even without nitration to form the intended 2,2'-dintrobiimidazole species. The successful results from biotests with Ru-bis(2MeIm) complexes (Chapter 3), led to the development of the analgous 2,2'-dimethyl-4,4'-biimidazole complexes for study. In Chapter 5, the reactions of imidazole-4-carboxylic acid and other N -heterocyclic carboxylic acids with Ru (III) precursors are described, as are the attempted syntheses of new 2-nitroimidazole-4-carboxylic acid derivatives. In Chapter 6, the results from the MTT assay for many of the complexes described in Chapters 3-5 will be discussed, while in Chapter 7, the results of Ru-uptake and -DNA binding experiments for several Ru complexes are reported and discussed. A monoclonal antibody binding assay is also discussed and the results of this assay with both EF5 and triF5 are presented. Although general conclusions will be included at the end of each individual chapter, in Chapter 8 some general conclusions about this thesis work will be presented. Directions for future research on this topic will also be discussed.

## Chapter 2

## General Experimental Procedures, and Syntheses of Ruthenium Precursor Complexes

### 2.1 Chemicals

### 2.1.1 Ligand Precursors

Imidazole (Im), 1-methylimidazole (1MeIm), 2-methylimidazole (2MeIm), 4methylimidazole (4MeIm), metronidazole (metro), 2-nitroimidazole ( $2 \mathrm{NO}_{2} \mathrm{Im}$ ), 4nitroimidazole ( $4 \mathrm{NO}_{2} \mathrm{Im}$ ), 3-nitro-1,2,4-triazole ( $3 \mathrm{NO}_{2}$ tri), 4-(hydroxymethyl)imidazole, imidazole-4-carboxylic acid ( $\mathrm{Im}-\mathrm{CO}_{2} \mathrm{H}$ ), pyridine-2-carboxylic acid (Hpic), 3-hydroxy-1,2-dimethyl-4-pyridone (HMepyr) and imidazole-4,5-dicarboxylic acid were purchased from Aldrich and used as received. 4,4'-Biimidazolium trifluoroacetate ( $\mathrm{H}_{2}$ biim) and 2,2'-dimethyl-4,4'-biimidazolium trifluoroacetate $\left(\mathrm{H}_{2} \mathrm{Me}_{2}\right.$ biim) were synthesized using modified literature procedures ${ }^{1}$ (Sections 4.8.2-4.8.11). 2-(2-Nitro-1-H-imidazol-1-yl)N -(2,2,3,3,3-pentafluoropropyl) acetamide (EF5) and 2-(3-nitro-1-H-triazol-1-yl)-N-(2,2,3,3,3-pentafluoropropyl) acetamide (triF5) were synthesized using a modified literature procedure ${ }^{2}$ (Sections 3.6 .2 and 3.6.3, respectively). 3-Nitro-1,2,4-triazole-5carboxylic acid (HCANT) was also synthesized using a modified literature procedure ${ }^{3}$ (Section 5.6.1). 3-Hydroxy-2-methyl-4-pyrone (maltol) (Cultor Food Science) and 2-ethyl-3-hydroxy-4-pyrone (ethylmaltol) (Pfizer Food Science) were donated by Dr. C. Orvig.

### 2.1.2 Solvents

Reagent grade DMF, DMSO, $\mathrm{MeCN}, \mathrm{CHCl}_{3}$, and EtOAc were purchased from Fisher Scientific and used as received. Other solvents (also purchased form Fisher) were dried and distilled prior to use: EtOH (distilled from Mg ), MeOH (distilled from Mg ), $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ (distilled from $\mathrm{CaH}_{2}$ ), $\mathrm{Et}_{2} \mathrm{O}$ (distilled from Na ), hexanes (distilled from Na ), THF (distilled from Na ), and acetone (distilled from $\mathrm{K}_{2} \mathrm{CO}_{3}$ ). Deuterated solvents $\mathrm{CDCl}_{3}$,
$\mathrm{CD}_{2} \mathrm{Cl}_{2}, \mathrm{CD}_{3} \mathrm{OD}, \mathrm{D}_{2} \mathrm{O}$, acetone- $d_{6}$, and dmso- $d_{6}$ were purchased form Cambridge Isotope Laboratories and used without further drying or purification.

### 2.1.3 Gases

$\mathrm{N}_{2}$ (medical grade), Ar, compressed air, and $\mathrm{H}_{2}$ (extra dry) were purchased from Praxair and used as received.

### 2.1.4 Biological Reagents

Materials used in the biological experiments are listed in Sections 6.2.1 and 7.2.1.

### 2.1.5 Other reagents

2,2,3,3,3-Pentafluoropropylamine was purchased from Interchim and Lancaster Synthesis. It was also prepared in small amounts according to a literature procedure. ${ }^{4,5}$ Trifluoromethane sulphonic acid (triflic acid), ferrocene ( $\mathrm{FeCp}_{2}$ ), bis(pentamethylcyclopentadienyl)iron(II) $\quad\left(\mathrm{FeCp}_{2}\right)$, tetrabutylammonium hexafluorophosphate (TBAP), potassium tert-butoxide, chlorotriphenylmethane (trityl chloride), N -methylmorpholine (NMM) and chloroacetyl chloride were purchased from Aldrich and used as received. $\mathrm{RuCl}_{3} \cdot 3 \mathrm{H}_{2} \mathrm{O}$ was kindly donated by Colonial Metals Inc., and had a Ru composition of $39 \%$. All other chemicals were used as received unless otherwise stated.

### 2.2 Analytical Techniques and Instrumentation

### 2.2.1 Nuclear Magnetic Resonance Spectroscopy

1D NMR spectra were recorded on Bruker AV300 ( $\left.{ }^{1} \mathrm{H},{ }^{19} \mathrm{~F},{ }^{13} \mathrm{C}\right)$, Bruker AV400 $\left({ }^{1} \mathrm{H},{ }^{13} \mathrm{C}\right)$, Bruker ARX200 $\left({ }^{1} \mathrm{H},{ }^{19} \mathrm{~F}\right)$, Bruker ARX400 $\left({ }^{1} \mathrm{H},{ }^{19} \mathrm{~F}\right)$ and Bruker AC200F $\left({ }^{1} \mathrm{H}\right.$, ${ }^{19} \mathrm{~F},{ }^{13} \mathrm{C}$ ) spectrometers. The AC200F spectrometer was typically used for testing ligand samples as many of the complexes were paramagnetic and required a wider sweep width to record their NMR spectra, typically 150 ppm for ${ }^{1} \mathrm{H}$ spectra, than the AC 200 F could provide, and therefore their spectra were recorded on the AV300 and 400 spectrometers. All ${ }^{1} \mathrm{H}$ NMR and ${ }^{19} \mathrm{~F}$ NMR spectra performed during my stay at the TU Berlin were
recorded on the ARX200 or ARX400 spectrometers. ${ }^{1} \mathrm{H}-{ }^{1} \mathrm{H}$ COSY and ${ }^{1} \mathrm{H}-{ }^{13} \mathrm{C}$ HMQC experiments were performed on the Bruker AV300 and AV400 spectrometers. Low temperature ${ }^{1} \mathrm{H}$ NMR spectra were all recorded on the AV300 spectrometer. The peaks are described in this thesis as observed in the spectra: $\mathrm{s}=\operatorname{singlet}, \mathrm{d}=$ doublet, $\mathrm{t}=$ triplet, $\mathrm{q}=$ quartet, $\mathrm{br}=$ broad, and $\mathrm{m}=$ multiplet. ${ }^{1} \mathrm{H}$ NMR spectra were referenced using the residual protonated solvent signals: $7.24\left(\mathrm{CDCl}_{3}\right), 5.32\left(\mathrm{CD}_{2} \mathrm{Cl}_{2}\right), 4.65\left(\mathrm{D}_{2} \mathrm{O}\right), 3.30$ $\left(\mathrm{CD}_{3} \mathrm{OD}\right), 2.49$ (dmso- $d_{6}$ ) and 2.04 (acetone- $d_{6}$ ). ${ }^{13} \mathrm{C}$ NMR spectra were referenced to the ${ }^{13} \mathrm{C}$ solvent signal: $77.0\left(\mathrm{CDCl}_{3}\right)$ and $53.8\left(\mathrm{CD}_{2} \mathrm{Cl}_{2}\right)$.

MestRe-C (Magnetic Resonance Companion, Version 1.5.0) was used to process the raw data for spectra obtained on the AC200F NMR spectrometer. For all other spectrometers, Win-NMR was used to analyze and process the spectral data.

Determination of $\mu_{\text {eff }}$ for $\mathrm{Ru}(I I I)$ paramagnetic complexes and the corresponding number of unpaired electrons for these complexes was performed using the Evans method at r.t. ${ }^{6}$ This technique measures the shift of the residual solvent signal due to the presence of the paramagnetic complex. The signal is typically shifted downfield. The complex solution was placed inside a melting point capillary that was subsequently flame-sealed and suspended inside a standard NMR tube containing only the deuterated solvent (Figure 2.1). Typically, the complex is in the NMR tube and the pure solvent

Figure 2.1 NMR set-up for performing the Evans method ${ }^{6}$ determination of $\mu_{\text {eff. }}$. The capillary is flame-sealed after being filled with a solution of known complex concentration, and lowered into an NMR tube using Teflon tape that allows for easy retrieval of the sample.
in the capillary; however, because of limited quantities of some samples and overlapping signals' in the solvent region from the complex, it was decided to place the complex solution in the capillary. Because of paramagnetic broadening of multiplet solvent signals, only solvents with sharp residual singlet signals were used for these measurements, i.e. $\mathrm{CDCl}_{3}$ or $\mathrm{CD}_{2} \mathrm{Cl}_{2}$. The values for $\Delta v$ were determined using the AV300 spectrometer and, from these values, $\mu_{\text {eff }}$ was calculated using the following equations (Equations 2.1-2.4). ${ }^{6,7}$ The diamagnetic correction value, $\chi_{L}$, was calculated from literature values for each ligand. ${ }^{8}$

$$
\chi_{\mathrm{g}}=\frac{3 \Delta v}{4 \pi v_{\mathrm{o}} \mathrm{~m}}+\chi_{\mathrm{o}} \quad \begin{align*}
& \mathrm{m}=\text { concentration of sample }(\mathrm{g} / \mathrm{mL}) \\
& \Delta v=\text { peak separation }(\mathrm{Hz}) \\
& \\
& v_{\mathrm{o}}=\text { frequency of spectrometer }(\mathrm{Hz}) \\
& \chi_{\mathrm{o}}=\text { mass susceptibility of solvent } \tag{Eq.2.1}
\end{align*}
$$

$$
\begin{array}{lll}
\chi_{M}^{\prime}=\chi_{M}-\sum \chi_{L} & \chi_{M}^{\prime}= & \text { mass susceptibility of metal ion } \\
& \chi_{L}= & \text { diamagnetic correction for }  \tag{Eq.2.3}\\
& \text { ligands }
\end{array}
$$

$$
\chi_{\mathrm{M}}=\chi_{\mathrm{g}} \mathrm{M} \quad \mathrm{M}=\begin{align*}
& \text { compound molecular weight }  \tag{Eq.2.2}\\
& (\mathrm{g} / \mathrm{mol})
\end{align*}
$$

$$
\begin{array}{lll}
\mu_{\text {eff }}=2.84 \sqrt{\chi_{\mathrm{M}}^{\prime} \mathrm{T}}=\sqrt{\mathrm{n}(\mathrm{n}+2)} & \mathrm{T}= & \text { absolute temperature }(\mathrm{K})  \tag{Eq.2.4}\\
& \mathrm{n}= & \text { number of unpaired } \mathrm{e}^{-} \text {on metal } \\
& \text { ion }
\end{array}
$$

### 2.2.2 Infrared Spectroscopy

Infrared spectra were recorded at UBC on an ATI Matson Genesis or BomemMichelson MB-100 FT-IR spectrometer. At the TU Berlin, spectra were recorded by Nicolet on a Typ Magna-IR 750 spectrometer. Spectra were recorded as KBr pellets and are reported in wavenumbers ( $\pm 4 \mathrm{~cm}^{-1}$ ) with selected functional groups assigned based on data for similar, previously reported complexes (see, for example, Section 5.3.2), ${ }^{9}$ and on references from standard IR textbooks. ${ }^{10,11}$

### 2.2.3 Mass Spectrometry

Mass spectral data were collected in the Mass Spectrometry laboratory at UBC under the supervision of Dr. G. Eigendorf and Dr. Y. Ling. The spectra were measured on a Kratos Concept IIHQ liquid secondary ion mass spectrometer, a Bruker Esquire electrospray (ESI ion trap) spectrometer and a Micromass LCT electrospray time of flight (ESI TOF) spectrometer. At the TU Berlin, mass spectra were collected on a Varian double focussed MS - Typ 311 A/AMD. $\mathrm{M}^{+}$is defined as the positive molecular ion of a given species and does not include the mass of solvated molecules or counter anions (e.g. for $\left.\left[\mathrm{Ru}(\mathrm{ma})_{2}(1 \mathrm{MeIm})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3} \cdot \mathrm{CH}_{2} \mathrm{Cl}_{2}, \mathrm{M}^{+}=\left[\mathrm{Ru}(\mathrm{ma})_{2}(1 \mathrm{MeIm})_{2}\right]^{+}\right)$.

### 2.2.4 UV-Visible Spectroscopy

UV-Vis spectra were recorded on an HP 8452A diode array spectrophotometer and are reported as $\lambda_{\text {max }}( \pm 3 \mathrm{~nm})\left(\varepsilon_{\max } \times 10^{-3}, \mathrm{M}^{-1} \mathrm{~cm}^{-1}\right)$.

### 2.2.5 Cyclic Voltammetry

Cyclic Voltammetry was performed on selected compounds in solutions of 0.1 M TBAP in degassed MeCN under a flow of $\mathrm{N}_{2}$. Voltammograms were recorded on a Pine Biopotentiostat, model AFCBP1, and processed using the accompanying software Pinechem v2.00. Compounds were scanned at $100 \mathrm{mV} / \mathrm{s}$ between -2 V and +2 V . The home-made cell used to perform these measurements (Figure 2.2) contained a Pt wire working electrode, a Pt wire counter electrode, and a silver wire reference electrode. $\mathrm{FeCp}_{2}$ and $\mathrm{FeCp}_{2}^{*}$ were used as internal standards $\left(\mathrm{E}_{1 / 2}\left(\mathrm{Fe}^{\mathrm{III/II}}\right)=0.40\right.$ and -0.19 V vs. SCE in MeCN, respectively). ${ }^{12}$ The electrodes were cleaned with conc. $\mathrm{HNO}_{3}$ before use, then rinsed with water and acetone, and dried at $100^{\circ} \mathrm{C}$. A voltammogram was then recorded with just solvent and electrolyte to ensure a flat baseline before repeating the CV measurement with the sample. The sample solution was scanned once without $\mathrm{FeCp}_{2}$, then again after $\mathrm{FeCp}_{2}$ had been added, this procedure being repeated to ensure values for the reduction potentials, $\mathrm{E}_{1 / 2}$, were reproducible. The $\mathrm{E}_{1 / 2}$ values are calculated as the average of the oxidation and reduction peaks $\left(\mathrm{E}_{1 / 2}=\left(\mathrm{E}_{\text {p.c. }}+\mathrm{E}_{\text {a.c. }}\right) / 2\right)$, and are reported as the average of two or more values for each compound ( $\pm 4 \mathrm{mV}$ ). The
reported values are calculated as follows: $\mathrm{E}_{1 / 2}$ (compound) in mV vs. SCE in $\mathrm{MeCN}=$ $400-\mathrm{E}_{1 / 2}\left(\mathrm{FeCp}_{2}\right)+\mathrm{E}_{1 / 2}$ (observed).

Figure 2.2 Cyclic Voltammetry cell used with Pt wire counter and working electrodes, and an Ag wire reference electrode.

### 2.2.6 Conductivity

Conductivity measurements were performed using a Serfass conductance bridge model RCM151B (Arthur H. Thomas Co. Ltd.) connected to a 3403 cell (Yellow Springs Instrument Co.). The cell was calibrated using a 0.0100 M KCl solution with a molar conductance ( $\Lambda_{\mathrm{M}}$ ) of $141.3 \Omega^{-1} \mathrm{~cm}^{2} \mathrm{~mol}^{-1}$ at $25{ }^{\circ} \mathrm{C}$ and a cell constant of $1.016 \mathrm{~cm}^{-1}$ (measurement of the cell constant was performed by another group member). ${ }^{13,14}$ Solutions to be tested were prepared at $10^{-3} \mathrm{M}$. Values in this thesis are reported as $\Lambda_{\mathrm{M}}$ $\left(\Omega^{-1} \mathrm{~cm}^{2} \mathrm{~mol}^{-1}\right) .{ }^{14}$

### 2.2.7 X-Ray Analysis

Four X-ray crystal structures were determined by Dr. B. O. Patrick in the X-ray crystallographic laboratory at UBC on a Rigaku/ADSC CCD area detector with graphite
monochromated $\mathrm{MoK} \alpha$ radiation (see Appendices 1-4). One X-ray crystal structure was determined by Dr. P. Escarpa at the TU Berlin on a Siemens Smart CCD area detector with graphite monochromated $\mathrm{MoK} \alpha$ radiation (see Appendix 5).

### 2.2.8 Elemental Analysis

Elemental analyses were performed at UBC by Dr. P. Borda and M. Lakha on a Carlo Erba Instruments EA 1106 CHN -O elemental analyzer. Some samples were also analyzed by Mr. M. K. Yang of the SFU Chemistry Department and by Canadian Microanalytical Services Ltd.

### 2.2.9 Biological Analysis

Biological assays were performed in the biological services laboratory of the chemistry department at UBC under the supervision of Dr. E. Polishchuk, with the exception of the antibody binding assay which was performed at the BC Cancer Research Centre in the laboratory of Dr. K Skov. A discussion of biological techniques will be reserved for Chapters 6 and 7, at which point the techniques used will be discussed in detail along with the general experimental procedures for the biological assays.

### 2.3 Chromatographic Techniques

Reactions for the syntheses of both ligands and metal complexes were monitored by TLC. The reaction mixtures were typically viewed under a UV lamp (Mineralight ${ }^{\circledR}$ Lamp Model UVG-54 short-wave UV-254 nm). For imidazoles and other compounds that could not be seen under the UV lamp, the developed TLC strips were exposed to $\mathrm{I}_{2}$ to visualize the remaining bands. Solvent combinations, including volume ratios, are listed in brackets as follows: e.g. $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}: \mathrm{MeOH}, 10: 1\right)$.

Many samples were purified using column chromatography or, more commonly, preparative thin layer chromatography. For columns, silica gel (230-400 mesh, Silicycle) was added to the eluent, the mixture stirred for $\sim 30$ seconds, and then slowly poured into the glass column (plugged with glass wool just above the stopcock to prevent silica from
pouring out the bottom) to avoid forming air bubbles. The column was then eluted under a positive pressure of $\mathrm{N}_{2}$ until the solvent level reached the top of the silica gel. The compound to be purified was then dissolved in a minimum amount of eluent and the solution then added to the top of the column with care taken not to disturb the top of the column. The solvent level was again lowered to the top of the silica gel. A layer of approximately 5 mm of silica gel was then added to the top of the column to prevent the compound from migrating back up into the solvent reservoir before the eluent was added and the column eluted.

For preparative TLC, a complex was dissolved in a minimum amount of eluent and the solution then loaded onto the TLC plate $(20 \mathrm{~cm} \times 20 \mathrm{~cm} \times 1000 \mu \mathrm{~m}$ thick, Uniplate from Analtech). Loading consisted of slowly streaking the solution across the plate forming a line about 1 cm in height centred approximately 1 inch from the bottom of the plate, and leaving approximately $2-3 \mathrm{~cm}$ between the line edge and the plate edge on either side of plate. The compounds were loaded slowly to prevent broadening of the line of streaked solution, using up to 150 mg of sample on a single plate. The plates were dried in air for 30 min before being developed to prevent streaking and improve separation (Figure 2.3).

Figure 2.3 Preparative TLC chamber with silica gel plate.

### 2.4 Ruthenium Precursors

### 2.4.1 $\mathrm{RuCl}_{3} \cdot \mathbf{3} \mathrm{H}_{2} \mathrm{O}$

This starting material, as stated in Section 2.1.5, was generously donated by Colonial Metals Inc. The actual oxidation state of the metal is likely a mixture of $\mathrm{Ru}^{\text {III }}$ and $\mathrm{Ru}^{\text {IV }} \cdot{ }^{15,16}$ The material comes with a certificate of authenticity stating a Ru content of $39 \%$ which agrees with the formulation of $\mathrm{RuCl}_{3} \cdot 3 \mathrm{H}_{2} \mathrm{O}$; however, the sample is highly hygroscopic and readily absorbs water if left exposed to air.

### 2.4.2 $\left[\mathrm{Ru}(\mathrm{DMF})_{6}\right]\left[\mathrm{CF}_{3} \mathrm{SO}_{3}\right]_{3}$

This complex was synthesized using a modified version of the procedure published by Judd et al. ${ }^{17}$ A solution of $\mathrm{RuCl}_{3} \cdot 3 \mathrm{H}_{2} \mathrm{O}(0.50 \mathrm{~g}, 1.9 \mathrm{mmol})$ in DMF ( 40 mL ) was refluxed under a flow of $\mathrm{H}_{2}$ for 3 h . The initially brown solution eventually became blue. To the blue solution was added $\mathrm{AgCF}_{3} \mathrm{SO}_{3}(2.20 \mathrm{~g}, 8.6 \mathrm{mmol})$, and the resulting solution was then refluxed for 1 h under $1 \mathrm{~atm} \mathrm{~N}_{2}$. The mixture was then cooled in an ice-bath and then filtered to remove AgCl . The resulting filtrate was reduced in volume under vacuum at $80^{\circ} \mathrm{C}$ to $\sim 10 \mathrm{~mL}$, when 100 mL of EtOAc was added. The resulting yellow precipitate was then collected by filtration, washed with $\mathrm{Et}_{2} \mathrm{O}(3 \times 5 \mathrm{~mL})$, and then dried under vacuum for 24 h at $78{ }^{\circ} \mathrm{C}$. Yield: $1.60 \mathrm{~g}(85 \%)$. ${ }^{1} \mathrm{H}$ NMR (dmso- $d_{6}$ ): $\delta 22.46,19.73\left(\mathrm{~s}, \mathrm{CH}_{3}\right)$. IR ( KBr ): $1650(\mathrm{C}=\mathrm{O})$. Anal. Calcd for $\mathrm{C}_{21} \mathrm{H}_{42} \mathrm{~F}_{9} \mathrm{~N}_{6} \mathrm{O}_{15} \mathrm{~S}_{3} \mathrm{Ru}: \mathrm{C}$, $25.56 ;$ H, 4.26 ; N, 8.52. Found: C, 25.22; H, 4.24; N, 8.46. The ${ }^{1} H$ NMR and IR data agree with those previously reported. ${ }^{17,18}$

### 2.4.3 cis $-\mathrm{RuCl}_{2}(\mathrm{DMSO})_{3}(\mathrm{DMSO})$

This complex was synthesized according to the procedure of Evans et al. ${ }^{19}$ A brown solution of $\mathrm{RuCl}_{3} \cdot 3 \mathrm{H}_{2} \mathrm{O}(0.80 \mathrm{~g}, 3.1 \mathrm{mmol})$ in DMSO ( 10 mL ) was stirred and refluxed at $180^{\circ} \mathrm{C}$ for 10 min , during which time the solution became red and then yellow. The yellow solution was then cooled to r.t., and acetone ( 50 mL ) was added with continued stirring. Over 20 min a yellow precipitate formed. The mixture was filtered
and the yellow solid washed with acetone ( $3 \times 10 \mathrm{~mL}$ ), and then dried under vacuum at $78{ }^{\circ} \mathrm{C}$ for 48 h . Yield: $0.92 \mathrm{~g}(62 \%) .{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta 2.70\left(\mathrm{~s}, 6 \mathrm{H}, \mathrm{CH}_{3} \mathrm{SO}\right) ; 3.30$, $3.41,3.47,3.50\left(\mathrm{~s}, 18 \mathrm{H}, \mathrm{C} H_{3} \mathrm{SO}\right)$. LR-MS (+LSIMS, thioglycerol): $485\left(\mathrm{M}^{+}\right), 449\left(\mathrm{M}^{+}-\right.$ $\mathrm{Cl}), 371\left(\mathrm{M}^{+}-\mathrm{Cl}\right.$ - DMSO). IR (KBr): $916(\underline{\mathrm{O}}=\mathrm{S}) ; 1096,1120(\underline{\mathrm{~S}}=\mathrm{O})$. Anal. Calcd for $\mathrm{C}_{8} \mathrm{H}_{24} \mathrm{O}_{4} \mathrm{~S}_{4} \mathrm{Cl}_{2} \mathrm{Ru}: \mathrm{C}, 19.83 ; \mathrm{H}, 4.99$. Found: C, 20.04; H, 4.96. The ${ }^{1} \mathrm{H}$ NMR and IR data are in agreement with those in the literature. ${ }^{19}$

### 2.4.4 $\quad \mathrm{K}_{3}\left[\mathrm{RuCl}_{6}\right]$

This compound was synthesized from a literature procedure. ${ }^{20}$ A solution of $\mathrm{RuCl}_{3} \cdot 3 \mathrm{H}_{2} \mathrm{O}(1.00 \mathrm{~g}, 3.82 \mathrm{mmol})$ in $\mathrm{MeOH}(50 \mathrm{~mL})$ was refluxed under a stream of $\mathrm{H}_{2}$. After 3 h the brown solution became green. $\mathrm{KCl}(0.90 \mathrm{~g}, 12 \mathrm{mmol})$ was then added and the mixture was refluxed in air for 3 h . As the KCl dissolved, a brown precipitate formed, and this was collected by filtration and recrystalized from 12 M HCl . The product was then washed with $\mathrm{MeOH}(2 \times 10 \mathrm{~mL})$ and dried under vacuum for 24 h at 78 ${ }^{\circ} \mathrm{C}$. Yield $1.22 \mathrm{~g}(74 \%)$. UV-Vis ( 12 M HCl ) 348 (3.41), 311 (3.31), 229 (4.38). The UV-Vis data agree with the literature values. ${ }^{20}$

### 2.4.5 $\quad \mathrm{Ru}_{2}\left(\mathrm{CH}_{3} \mathrm{COO}\right)_{4} \mathrm{Cl}$

The complex was synthesized via a modified version of the procedure by Stephenson and Wilkinson. ${ }^{21}$ A brown solution of $\mathrm{RuCl}_{3} \cdot 3 \mathrm{H}_{2} \mathrm{O}(1.00 \mathrm{~g}, 3.82 \mathrm{mmol})$ in glacial acetic acid ( 30 mL ) and acetic anhydride ( 5 mL ) was refluxed in air for 2 h . The solution slowly developed a dark green colour and after 2 h was cooled to r.t. and filtered to remove a black precipitate. The solution was then refluxed for an additional 6 h at which time the green solution was cooled to r.t. and left standing in air for 16 h . Brown crystals were then removed from the solution by filtration, washed with cold acetic acid $\left(2 \times 5 \mathrm{~mL}, 0^{\circ} \mathrm{C}\right)$ and $\mathrm{Et}_{2} \mathrm{O}(2 \times 5 \mathrm{~mL})$ and then dried for 24 h at $78^{\circ} \mathrm{C}$. Yield: $0.65 \mathrm{~g}(72$ \%). LR-MS (+ESI): $440\left(\mathrm{M}^{+}-\mathrm{Cl}\right)$. IR ( KBr ): 1445, $1401\left(\mu-\mathrm{MeCO}_{2}{ }^{-}\right)$. Anal. Calcd for $\mathrm{C}_{8} \mathrm{H}_{12} \mathrm{O}_{8} \mathrm{ClRu}_{2}$ : C, 20.27; $\mathrm{H}, 2.53$. Found: C, 20.43; H, 2.62.

## Chapter 3

## Synthesis and Characterization of Ruthenium(III) Maltolato and Imidazole Complexes

### 3.1 Introduction

This chapter examines the synthesis and characterization of several new Ru (III) maltolato and imidazole complexes. $\mathrm{Ru}(\mathrm{ma})_{3}$ was first synthesized by Greaves and Griffith in 1988, ${ }^{1}$ but the ${ }^{1} \mathrm{H}$ NMR spectrum for this paramagnetic complex was not reported; such data are quite useful in determining structural information about this complex and its derivatives. The ${ }^{1} \mathrm{H}$ NMR spectra of paramagnetic complexes can exhibit chemical shifts far removed from the "expected" diamagnetic ones. ${ }^{2}$ Paramagnetic shifts can range from a few Hz to $>100 \mathrm{ppm}$, and the signals are often broad and of relatively low intensity. Their appearance varies greatly depending on the geometry and nature of the ligands present. ${ }^{3,4}$ For these reasons, ${ }^{1} \mathrm{H}$ NMR spectra of paramagnetic complexes can be difficult to interpret. In this Chapter, the $1 \mathrm{D}{ }^{1} \mathrm{H}$ NMR and 2D ${ }^{1} \mathrm{H}^{1} \mathrm{H}$ COSY and ${ }^{1} \mathrm{H}-{ }^{13} \mathrm{C}$ HMQC spectra of some Ru (III) complexes are examined in order to elucidate structural information of the species in solution.

Anderson and Beauchamp have studied the paramagnetic ${ }^{1} \mathrm{H}$ NMR spectra of $\mathrm{Ru}(\mathrm{III})$ complexes of imidazole and methyl-imidazoles, ${ }^{5-7}$ where 2-deuteroimidazole was used to make spectral assignments. ${ }^{8}$ A general trend was observed in the shift of the imidazole protons with $H(5)<H(4)<H(2)$, the $H(2)$ signal being shifted the farthest upfield. As will be discussed in Section 3.3, methyl signals on both maltolato and imidazole ligands shift downfield, while imidazole proton signals shift upfield.

Eaton et al. have performed in depth studies of paramagnetic tropolonato species, ${ }^{9}$ and the ${ }^{1} \mathrm{H}$ NMR data for Ru (tropolonato) $)_{3}$ have been used in assigning the maltolato and ethylmaltolato spectra presented in Section 3.2. In this thesis work, no distinct pattern has been observed for the chemical shifts of the maltolato ring protons; in fact, these proton signals are generally not observed in the spectra of the mixed maltolato imidazole complexes.

In addition to maltolato complexes with ancillary imidazole and nitroimidazole ligands, this work was expanded to investigate 3-nitro-1,2,4-triazoles (Figure 3.1) as well because nitrotriazoles, like nitroimidazoles, can be effective radiosensitizers. ${ }^{10}$ A triazole analogue of EF5 was synthesized and will be discussed in more detail in Section 3.3 and Chapter 7.

Imidazole

3-Nitro-1,2,4-triazole

### 3.2 Investigation of $\mathbf{R u}(\mathrm{ma})_{3}$ and $\mathrm{Ru}(\mathrm{Ema})_{3}$

### 3.2.1 Characterization and Solution NMR Data for $\mathbf{R u}(\mathrm{ma})_{3}$ (1)

The synthesis of $\mathrm{Ru}(\mathrm{ma})_{3}$ (Figure 3.2) has been previously reported ${ }^{1}$ but, in this thesis work, its purification was modified to remove impurities (observed by TLC), thus improving the elemental analysis from that reported (Section 3.6.1). The IR data agreed with those reported ${ }^{1}$ and the mass spectrum showed the parent peak at 477 . The

Figure 3.2 Molecular structure of $m e r-\mathrm{Ru}(\mathrm{ma})_{3}(\mathbf{1})$.
conductivity of an aqueous solution of 1 was $25 \Omega^{-1} \mathrm{~cm}^{2} \mathrm{~mol}^{-1}$, at the upper limit for a nonelectrolyte, ${ }^{11}$ suggesting that a small amount of the maltolato ligand may be dissociating in solution. The structure of the red complex was determined in this department by X-ray crystallography (Figure 3.3), but disorder in the crystal (grown from slow evaporation of a $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ :acetone, $1: 1$ solution) prevented full refinement of the structure (see Appendix Al for structure details). Nevertheless, the complex crystallizes in the mer-configuration, and the solution ${ }^{1} \mathrm{H}$ NMR spectrum at r.t. in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$ also shows the mer-configuration as the primary isomer.

Figure 3.3 ORTEP diagram of mer- $\mathrm{Ru}(\mathrm{ma})_{3}(\mathbf{1})$ with $33 \%$ probability thermal ellipsoids (see Appendix A1 for details).

The ${ }^{1} \mathrm{H}$ NMR spectrum (Figure 3.4) clearly shows nine singlets assigned to mer- 1 and an additional 3 trace singlets that are assigned to the fac-isomer $(\delta 33.8,1.6,1.0) .{ }^{1} \mathrm{H}$ NMR was performed in $\mathrm{CDCl}_{3}, \mathrm{CD}_{2} \mathrm{Cl}_{2}, \mathrm{CD}_{3} \mathrm{OD}, \mathrm{D}_{2} \mathrm{O}$ and acetone- $d_{6}$ and in each case the mer-isomer was observed. The three resonances assigned to the fac-isomer are only observed in $\mathrm{CDCl}_{3}$ and $\mathrm{CD}_{2} \mathrm{Cl}_{2}$ in which $\mathbf{1}$ is more soluble, and varied proportionally in intensity between different samples, giving further evidence that their assignment to a single species is correct.

Figure 3.4 ${ }^{\mathrm{I}} \mathrm{H}$ NMR spectrum ( 300 MHz , 298 K ) of $\mathrm{Ru}(\mathrm{ma})_{3}$ (1) in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$. Resonances for the mer-isomer have been labelled and those for the facisomer have been identified with boxes.

The signals shifted the farthest downfield, $\delta 43.2,41.0$ and 21.1, are for the Me groups on the maltolato ring, and this was confirmed by the ${ }^{1} \mathrm{H}-{ }^{1} \mathrm{H}$ COSY spectrum (Figure 3.5); these 3 signals showed no crosspeaks as expected for the Me groups, while the remaining 6 resonances each showed a mutual correlation to one of the other resonances, giving 3 pairs of singlets ( $\delta 11.8$ and $9.2,3.1$ and $-4.6,0.8$ and -0.9 ), one pair for the $H(5)$ and $H(6)$ protons for each maltolato ring. The resonances assigned to the solvent, $\mathrm{CDHCl}_{2}$, and to $\mathrm{H}_{2} \mathrm{O}$ also gave no crosspeaks, suggesting that these assignments are correct.

Figure 3.5 ${ }^{1} \mathrm{H}-{ }^{-1} \mathrm{H} \operatorname{COSY}$ spectrum ( $300 \mathrm{MHz}, 298 \mathrm{~K}$ ) of $\mathrm{Ru}(\mathrm{ma})_{3}(\mathbf{1})$ in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$. The signals downfield of $\delta 20$ are omitted as they showed no crosspeaks. The coupled pairs for $\mathrm{H}(5)$ and $\mathrm{H}(6)$ are highlighted with boxes.

The ${ }^{1} \mathrm{H}-{ }^{13} \mathrm{C}$ HMQC spectrum (Figure 3.6) provides further evidence for the ${ }^{1} \mathrm{H}$ assignments, as the 6 maltolato ring proton signals each give a crosspeak between $\delta 75$ and 175 in the ${ }^{13} \mathrm{C}$ NMR spectrum as expected for protons on an $\mathrm{sp}^{2}$-hybridized carbon. ${ }^{12}$ Two crosspeaks for the Me groups are also observed, that for the ${ }^{1} \mathrm{H}$ signal at $\delta$ 21.1, giving a ${ }^{13} \mathrm{C}$ crosspeak at $\delta-7$, the other for the trace fac-signal at $\delta 33.8$ giving rise

Figure 3.6 ${ }^{1} \mathrm{H}-{ }^{13} \mathrm{C}$ HMQC spectrum ( $300 \mathrm{MHz}, 298 \mathrm{~K}$ ) of $\mathrm{Ru}(\mathrm{ma})_{3}(\mathbf{1})$ in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$ with the ${ }^{13} \mathrm{C}$ spectrum on the left-hand side and the ${ }^{1} \mathrm{H}$ spectrum at the top. Some decomposition occurred in this sample leading to additional crosspeaks. The $H(5)$ and $H(6)$ protons, the solvent and two Me groups, which all show crosspeaks, are indicated with arrows.
to a ${ }^{13} \mathrm{C}$ crosspeak at $\delta-52$. Crosspeaks for the remaining two Me groups ( $\delta 41.0$ and 43.2) may be shifted too far upfield in the ${ }^{13} \mathrm{C}$ NMR spectrum, beyond $\delta-75$, to be detected. Additional signals in the ${ }^{1} \mathrm{H}$ NMR spectrum between $\delta 0-5$ result from slow decomposition of the sample in situ as the acquisition of the HMQC spectrum takes several hours. Although the decomposition products may be present in very small amounts, they can still give rise to relatively intense signals compared to those observed
for the paramagnetic complex. ${ }^{13} \mathrm{C}$ signals for these decomposition products are also not observed, but crosspeaks are seen between $\delta 0-40$ with the ${ }^{13} \mathrm{C}$ NMR spectrum. Only a signal ( $\delta 54$ ) for $\mathrm{CD}_{2} \mathrm{Cl}_{2}$ is observed in the ${ }^{13} \mathrm{C}$ NMR spectrum after 12 h ; however, a partial spectrum can be generated from the crosspeaks of the ${ }^{1} \mathrm{H}-{ }^{13} \mathrm{C}$ HMQC experiment, producing a spectrum that contains signals for those C -atoms that show correlation with signals in the ${ }^{1} \mathrm{H}$ NMR spectrum (Figure 3.7).

Figure 3.7 Partial ${ }^{13} \mathrm{C}$ NMR spectrum of $1(300 \mathrm{MHz}, 298 \mathrm{~K})$ in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$ generated as a positive projection of the $y$-axis from the ${ }^{1} \mathrm{H}-{ }^{13} \mathrm{C} \mathrm{HMQC}$ spectrum of $\mathbf{1}$. Only carbons that gave rise to crosspeaks in the 2D spectrum are observed (o denotes carbons attached to $\mathrm{H}(6)$ protons and denote those attached to $\mathrm{H}(5)$ protons).

The ${ }^{1} \mathrm{H}$ NMR spectrum of $\mathrm{Ru}(\mathrm{ma})_{3}$ was also recorded at lower temperatures (Table 3.1). These shifts can be plotted vs $1 / \mathrm{T}$ (Figures 3.8 and 3.9) and the intercept at $1 / T=0$ should give the value expected for a corresponding diamagnetic species. ${ }^{13}$ From the intercepts of Figure 3.7, it can be determined which of the six signals correspond to $H(5)$ and $H(6)$, because for free maltol, $\mathrm{H}(5)$ is observed at $\delta 6.4$ and $\mathrm{H}(6)$ at $\delta 7.7$. For each pair of singlets observed in the ${ }^{1} \mathrm{H}-{ }^{1} \mathrm{H}$ COSY spectrum of 1 , one can be assigned as $H(5)$ and the other as $H(6) . H(a)$ and $H(b)$ show correlation in Figure 3.5, and in Figure 3.8 give X-intercepts at $\delta 5.2$ and 8.2, respectively; from these values, $\mathrm{H}(\mathrm{a})$ can be
assigned as an $\mathrm{H}(5)$ proton, and $\mathrm{H}(\mathrm{b})$ as an $\mathrm{H}(6)$ proton. Similarly, $\mathrm{H}(\mathrm{c})$ and $\mathrm{H}(\mathrm{d})$ can be assigned as $\mathrm{H}(6)$ protons, and $\mathrm{H}(\mathrm{e})$ and $\mathrm{H}(\mathrm{f})$ can be assigned as $\mathrm{H}(5)$ protons. The Xintercepts for the Me groups in Figure 3.9 ( $\delta 14.3,10.0$ and 9.0) do not correlate well with the Me signal of free maltol ( $\delta 2.4$ ).

The ${ }^{1} \mathrm{H}$ NMR shift data were also used to determine $\mu_{\text {eff }}\left(1.52 \mathrm{BM}\right.$ at $\left.22{ }^{\circ} \mathrm{C}\right)$ using Evan's method. ${ }^{14}$

Table 3.1 Variable temperature chemical shifts of $\mathrm{Ru}(\mathrm{ma})_{3}(300 \mathrm{MHz})$ in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$ including values at $\mathrm{T}=\infty$, as determined by linear regression.

### 3.2.2 Characterization and Solution NMR Data for $\mathbf{R u}(E m a)_{3}(\mathbf{2})$

The general synthesis for $\mathrm{Ru}(\mathrm{Ema})_{3}(\mathbf{2})$ is the same as for $\mathbf{1}$, and $\mathbf{2}$ has also been characterized by elemental analysis, MS and IR spectroscopy. The 1D and 2D NMR spectra for $\mathbf{2}$ are more complicated than those for $\mathbf{1}$ because of the presence of an Et vs. Me group. $\mathrm{Ru}(E m a)_{3}$ also exists predominantly as the mer-isomer in solution based on comparison with the ${ }^{1} \mathrm{H}$ NMR spectrum for $\mathbf{1}$. The r.t. ${ }^{1} \mathrm{H}$ NMR spectrum for 2 (Figure 3.10) in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$ shows 6 resonances of roughly equal intensity shifted downfield past $\delta 15$, as opposed to the 3 seen in the ${ }^{1} \mathrm{H}$ NMR spectrum of 1 (Figure 3.4), and there are now two trace signals observed for the fac-isomer in the downfield region as opposed to the one seen for $\mathrm{Ru}(\mathrm{ma})_{3}$. The three resonances for the $\mathrm{Me}, \mathrm{H}(5)$ and $\mathrm{H}(6)$ protons for the fac-isomer of 2 are not observed, and presumably overlap with signals for the merisomer. The 6 major downfield signals are assigned to the 6 inequivalent protons of the three $\mathrm{CH}_{2}$ groups.

Figure 3.10 ${ }^{1} \mathrm{H}$ NMR spectrum of $\mathrm{Ru}(\mathrm{Ema})_{3}(\mathbf{2})(300 \mathrm{MHz}, 298 \mathrm{~K})$ in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$.

The resonances for the $\mathrm{CH}_{3}$ of the Et groups are also shifted downfield ( $\delta 4.9,4.8$, and 2.1 for 2 vs. $\delta 1.22$ for free ethylmaltol in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$ ), but by a considerably less amount than are the $\mathrm{CH}_{2}$ signals. The Me signals are distinguished from those of the maltolato ring protons and from the residual solvent signal using 2D NMR spectroscopy. The ${ }^{1} \mathrm{H}$ ${ }^{1} \mathrm{H}$ COSY spectrum clearly shows that there are again 3 pairs of singlets for the maltolato ring protons ( $\delta 12.5$ with $9.0,4.9$ with -4.9 , and 1.2 with -0.8 ) (Figure 3.11). The spectrum also shows pairs of signals for the $\mathrm{CH}_{2}$ groups (those signals shifted downfield of $\delta 15$ ) correlating with signals for the corresponding Me groups for each Ema ligand ( $\delta 40.1$ and 35.3 with $\delta 2.1, \delta 38.8$ and 33.4 with $\delta 4.9$, and $\delta 21.7$ and 18.9 with $\delta 4.8$ ). The ${ }^{1} \mathrm{H}^{-}{ }^{1} \mathrm{H}$ COSY spectrum also shows correlation between the two $\mathrm{CH}_{2}$ protons, but only for the signals at $\delta 21.7$ and 18.9. Although the resonances at $\delta 40.1$ and 35.3 do not give rise to mutual crosspeaks, they can be still be assigned to one $\mathrm{CH}_{2}$ group as they correlate with the same Me group ( $\delta 2.1$ ). The same holds true for the $\mathrm{CH}_{2}$ resonances at $\delta 38.8$ and 33.4 that give a crosspeak with the same Me resonance ( $\delta 4.9$ ).

As in the ${ }^{13} \mathrm{C}$ NMR spectrum of $\mathbf{1}$, that of 2 shows no signals for the complex, only a single resonance for $\mathrm{CD}_{2} \mathrm{Cl}_{2}(\delta 54)$. The ${ }^{1} \mathrm{H}-{ }^{13} \mathrm{C}$ HMQC spectrum, however,

Figure $3.11 \quad{ }^{1} \mathrm{H}-{ }^{1} \mathrm{H}$ COSY spectrum of $2(300 \mathrm{MHz}, 298 \mathrm{~K})$ in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$. a) Complete spectrum. b) Expansion showing correlation between $\mathrm{CH}_{2}$ protons shifted downfield for 2 of the ligands. c) Expansion showing correlation between $\mathrm{CH}_{2}$ and Me protons for the same two $\mathrm{CH}_{2}$ groups shown in (b). d) Expansion showing $\mathrm{H}(5)$ and $\mathrm{H}(6)$ correlations for all 3 ligands (blue boxes) as well as the $\mathrm{CH}_{2} / \mathrm{Me}$ and $\mathrm{CH}_{2} / \mathrm{CH}_{2}$ correlations for the third ligand not observed in (b) or (c) (purple boxes).
shows crosspeaks for many of the ${ }^{1} \mathrm{H}$ signals with the ${ }^{13} \mathrm{C}$ NMR spectrum of 2 (Figure 3.12). In particular, there are 6 signals observed between $\delta 75$ and 175 for the $\mathrm{H}(5)$ and $\mathrm{H}(6)$ protons on the maltolato ring, as for $\mathrm{Ru}(\mathrm{ma})_{3}$. No crosspeaks are observed for either the $\mathrm{CH}_{2}$ or $\mathrm{CH}_{3}$ of the ethyl groups. The partial ${ }^{13} \mathrm{C}$ NMR spectrum, as for 1 , can be generated for $\mathbf{2}$ from the HMQC spectrum.

Figure $3.12{ }^{1} \mathrm{H}-{ }^{13} \mathrm{C}$ HMQC spectrum ( $300 \mathrm{MHz}, 298 \mathrm{~K}$ ) of $\mathrm{Ru}(\text { Ema })_{3}(2)$ in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$ with the ${ }^{13} \mathrm{C}$ spectrum on the left-hand side and the ${ }^{1} \mathrm{H}$ spectrum at the top. Some decomposition occurred in this sample leading to additional crosspeaks. The $\mathrm{H}(5)$ and $\mathrm{H}(6)$ protons are indicated with arrows, as is the solvent. The ${ }^{1} \mathrm{H}$ NMR resonances downfield of $\delta 20$ have been omitted as no crosspeaks were observed in this region of the spectrum.

### 3.2.3 "Activation" of $\mathrm{Ru}(\mathrm{ma})_{3}$ with $\mathrm{CF}_{3} \mathrm{SO}_{3} \mathrm{H}-\quad$ Synthesis of $\left[\mathrm{Ru}(\mathrm{ma})_{2}(\mathbf{E t O H})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$ (3)

The reaction of $\mathrm{Ru}(\mathrm{ma})_{3}(\mathbf{1})$ with triflic acid under $\mathrm{N}_{2}$ was monitored in $\mathrm{CD}_{3} \mathrm{OD}$ (Figure 3.13). The $\mathrm{CD}_{3} \mathrm{OD}$ was degassed for one minute with $\mathrm{N}_{2}$ in an NMR tube, to which was added 10 mg of 1 . The ${ }^{1} \mathrm{H}$ NMR spectrum of the sample was recorded (Figure 3.12a), then the NMR tube was removed from the spectrometer and 1 equivalent of $\mathrm{CF}_{3} \mathrm{SO}_{3} \mathrm{H}$ was added to the solution of 1 , still under $\mathrm{N}_{2}$. This mixture was shaken vigorously for 2 min , and the spectrum of the mixture was then recorded (Figure 3.13b). The total time lapse between adding the triflic acid and recording the spectrum was 10 min . The sample was then left sitting at r.t. for an additional 50 min before recording the ${ }^{1} \mathrm{H}$ NMR spectrum of the solution mixture again (Figure 3.13c). In this reaction, loss of the signals for $\mathbf{1}$ was accompanied with generation of signals for a new $\mathrm{Ru}(I I I)$ complex, as well as signals for free maltol $[\delta 2.4(\mathrm{~s}, \mathrm{Me}), 6.4(\mathrm{~d}, \mathrm{H}(5))$, and $7.7(\mathrm{~d}, \mathrm{H}(6))]$. There is only one $\mathrm{Ru}(\mathrm{III})$ ma containing species present in solution after 1 h as evidenced by the single broad resonance at $\delta 45$, likely for trans- $\left[\mathrm{Ru}(\mathrm{ma})_{2}\left(\mathrm{CD}_{3} \mathrm{OD}\right)_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$ (see below).

When 1 was treated with triflic acid in EtOH in a synthetic reaction, the initially red solution darkened and, after 1 h , TLC analysis revealed that $\mathbf{1}$ had been quantitatively converted to a new product. The volume of this solution was then reduced and the complex precipitated from the solution on addition of $\mathrm{Et}_{2} \mathrm{O}$. This complex has been characterized by elemental analysis, MS, IR and ${ }^{1} \mathrm{H}$ NMR spectroscopies as $\left[\mathrm{Ru}(\mathrm{ma})_{2}(\mathrm{EtOH})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}(3)$. The parent peak is found in the mass spectrum as are peaks for the subsequent fragmentation loss of one and two EtOH ligands. The $\mathbb{I R}$ spectrum shows strong bands for the $\mathrm{C}=\mathrm{O}$ of ma and for $\mathrm{O}-\mathrm{H}$ of EtOH . The conductivity of an EtOH solution of $3\left(36 \Omega^{-1} \mathrm{~cm}^{2} \mathrm{~mol}^{-1}\right)$ was in the range for a 1:1 electrolyte. ${ }^{15}$

When $\mathbf{3}$ is dissolved in $\mathrm{CD}_{3} \mathrm{OD}$, the immediate ${ }^{1} \mathrm{H}$ NMR spectrum shows a single species (as evidenced by a single resonance for the ma-Me group); this then decomposes over 15 min to yield a spectrum for a complex identical to that formed from the in situ reaction (Figure 3.13c), with the exception that the free maltol signals are now absent and free EtOH signals are now present. The presence of only one Me signal for the maltolato ligand is consistent with a trans-isomer as observed with all the structurally characterized, Im-ma complexes described in the next section.

Figure 3.13 In situ formation of $\left[\mathrm{Ru}(\mathrm{ma})_{2}\left(\mathrm{CD}_{3} \mathrm{OD}\right)_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$ as shown by ${ }^{1} \mathrm{H}$ NMR spectroscopy, the broad downfield signal being characteristic of a transgeometry for the maltolato ligands (see text). a) $\mathrm{Ru}(\mathrm{ma})_{3}$ in $\mathrm{CD}_{3} \mathrm{OD}$ b) $\mathrm{Ru}(\mathrm{ma})_{3}$ in $\mathrm{CD}_{3} \mathrm{OD}+\mathrm{CF}_{3} \mathrm{COOH}$ after $\sim 10 \mathrm{~min}$ c) $\mathrm{Ru}(\mathrm{ma})_{3}$ in $\mathrm{CD}_{3} \mathrm{OD}+$ $\mathrm{CF}_{3} \mathrm{COOH}$ after $\sim 1 \mathrm{~h}$.

### 3.3 Reactions of $\operatorname{Ru}(\mathrm{ma})_{3}(1)$ and $\operatorname{Ru}(\mathrm{Ema})_{3}$ (2) with Imidazoles and Triazoles

### 3.3.1 Synthesis and Characterization of Imidazole and Triazole Complexes

Complexes of the form $\left[\mathrm{Ru}(\mathrm{ma})_{2}(\mathrm{~L})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$ discussed in this section can be divided into two groups, those without nitro groups: $\mathrm{L}=4 \mathrm{MeIm}(\mathbf{6}), \operatorname{Im}(7), 1 \mathrm{MeIm}(8)$, $2 \mathrm{MeIm}(10)$; and those with nitro groups: $\mathrm{L}=$ metro (4), EF5 (14), $2 \mathrm{NO}_{2} \operatorname{Im}(15)$, $4 \mathrm{NO}_{2} \operatorname{Im}(\mathbf{1 6}), \quad 3 \mathrm{NO}_{2}$ tri (17) and triF5 (18). Two additional complexes, $\left[\mathrm{Ru}(\mathrm{ma})(1 \mathrm{MeIm})_{4}\right]\left[\mathrm{CF}_{3} \mathrm{SO}_{3}\right]_{2}$ (9) and $\left[\mathrm{Ru}(\mathrm{ma})_{2}\right.$ (metro) $\left.(\mathrm{EtOH})\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$ (5) were also isolated. These complexes have been characterized generally by elemental analysis, mass spectrometry, and NMR and IR spectroscopies. The complexes $\mathbf{1 5 - 1 8}$ were insoluble in all matrices for LSIMS, and lacked sufficient solubility in applicable solvents to examine them by ESI-MS. Solid state MS techniques were not available in the department MS facility. Complexes $6,7,8$, and $\mathbf{1 0}$ (Figure 3.14) were synthesized by reacting $\mathbf{1}$ with one equivalent of triflic acid in EtOH at r.t., and then adding excess of the imidazole to the reaction mixture. All four complexes were purified using preparative TLC and isolated as red solids. MeOH solutions of each gave conductivity values in the range for 1:1 electrolytes. ${ }^{15}$ The elemental analyses for $\mathbf{6}$ and $\mathbf{8}$ indicate the presence of one $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ solvate, and in the case of 8 , the solvated $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ was detected by X-ray crystallography (Figure 3.16, Appendix A2).

Figure 3.14 Molecular structures for the trans-isomers of 4, 6-8 and $\mathbf{1 0}$.

The reaction between $1, \mathrm{CF}_{3} \mathrm{SO}_{3} \mathrm{H}$ and 4 equivalents of 1 MeIm in refluxing EtOH was followed by TLC. A blue species that increased in intensity over time became the major product after 48 h , and was isolated by preparative TLC ( $18 \%$ yield) and formulated as 9 (Figure 3.15). The reaction was repeated adding an 8 -fold excess of 1 MeIm and two equivalents of $\mathrm{CF}_{3} \mathrm{SO}_{3} \mathrm{H}$ instead of one; the percent yield of 9 after 48 h increased to $51 \%$. The conductivity of a MeOH solution of $9\left(273 \Omega^{-1} \mathrm{~cm}^{2} \mathrm{~mol}^{-1}\right)$ is in the range for a $2: 1$ electrolyte. ${ }^{15}$

Figure 3.15 Molecular structure of $\left[\mathrm{Ru}(\mathrm{ma})(1 \mathrm{MeIm})_{4}\right]\left[\mathrm{CF}_{3} \mathrm{SO}_{3}\right]_{2}(9)$.

4 (Figure 3.14) was synthesized by the same procedure as for $\mathbf{6}, 7,8$, and 10 , but with refluxing the reaction mixture for 6 h ; the product then precipitated when the solution was cooled. Work-up of the filtrate led to the isolation of a second, green product in low yield, 5. Elemental analysis and MS confirmed the formulations of $\mathbf{4}$ and 5. 4 was then subsequently crystallized by another member of our group, and the $\bar{X}$-ray structure determined that it was of a trans-configuration. ${ }^{16}$

Complexes 8 and 10 have also been characterized by X-ray crystallography (Figures 3.16 and 3.17 , respectively), and all three structures show trans-imidazole ligands and a centre of inversion at the Ru .

Figure 3.16 ORTEP diagram of the cation of trans$\left[\mathrm{Ru}(\mathrm{ma})_{2}(\mathrm{IMeIm})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3} \cdot \mathrm{CH}_{2} \mathrm{Cl}_{2}(\mathbf{8})$ with $50 \%$ probability thermal ellipsoids (see Appendix A2 for details).

Figure 3.17 ORTEP diagram of the cation of trans- $\left[\mathrm{Ru}(\mathrm{ma})_{2}(2 \mathrm{MeIm})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}(\mathbf{1 0})$ with $50 \%$ probability thermal ellipsoids (see Appendix A3 for details).

The Ru-N bond lengths for $\mathbf{1 0}$ might be expected to be longer than those for $\mathbf{8}$ as the $2-\mathrm{Me}$ group could give rise to steric interactions with the ma ligands: in $\mathbf{8}$, a $1-\mathrm{Me}$ derivative, the imidazole Me groups point away from the ma ligands and in $\mathbf{1 0}$ they point towards the ma ligands. However, there are no differences in the Ru-N bond lengths. Instead, the imidazole rings in $\mathbf{1 0}$ tilt to move the Me group away from the plane of the maltolato ligands (Figure 3.18). This can be seen by looking at the Ru-N(3)-C(2) and Ru-N(3)-C(4) angles (see Figure 3.19 for the atomic numbering scheme) in the structures of $\mathbf{8}$ and $\mathbf{1 0}$. For $\mathbf{8}$, these angles differ by less than one degree (Table 3.2), while for $\mathbf{1 0}$ these angles differ by 6.2 degrees.
a)

Figure 3.18 Diagram depicting the potential steric interaction between an Im-Me group and the ma plane for 10 . a) Steric interaction when coordinated symmetrically about $\mathrm{N}(3)$. b) Shows how tilting at the coordinated nitrogen removes this steric interaction by increasing the $\mathrm{Ru}-\mathrm{N}(3)-\mathrm{C}(2)$ bond angle and decreasing the Ru-N(3)-C(4) bond angle.

Figure 3.19 Template with numbering scheme for crystal structure information displayed in Table 3.2.

Complexes of the form $\left[\mathrm{Ru}(\mathrm{Ema})_{2}(\mathrm{~L})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$ were also synthesized from $\mathrm{Ru}(\mathrm{Ema})_{3}$ with $\mathrm{L}=$ metro (11), 4 MeIm (12) and $2 \mathrm{MeIm}(13)$. Again, complexes were characterized by elemental analysis, MS, and NMR and IR spectroscopies, while $\mathbf{1 1}$ was also characterized by X-ray crystallography (Figure 3.20). 11 was synthesized in the same manner as was 4 ; however, the observed green TLC band, likely containing $\left[\mathrm{Ru}(\mathrm{Ema})_{2}\right.$ (metro) $\left.(\mathrm{EtOH})\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$ (analogous to $\mathbf{5}$ ), did not generate an isolable solid. The structure of $\mathbf{1 1}$, like those for $4,{ }^{16} \mathbf{8}$ and $\mathbf{1 0}$, shows trans-imidazole ligands with a centre of inversion at Ru , and the distortion of bond angles at $\mathrm{N}(3)$, to relieve the steric interaction between the 2 -Me group and the ma-type ligands, is observed in the structures of $\mathbf{4}^{16}$ and $\mathbf{1 1}$, as was observed for $\mathbf{1 0}$ (Table 3.2).

Figure 3.20 ORTEP diagram of the cation of trans- $\left[\mathrm{Ru}(\mathrm{Ema})_{2}(\text { metro })_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$ (11) with $50 \%$ probability thermal ellipsoids (see Appendix A4 for details).
$\left[\mathrm{Ru}(\mathrm{ma})_{2}(\mathrm{~L})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}\left(\mathrm{~L}=2 \mathrm{NO}_{2} \operatorname{Im}(15), 4 \mathrm{NO}_{2} \operatorname{Im}(16), 3 \mathrm{NO}_{2}\right.$ tri (17)) were synthesized by adding an excess of the appropriate nitroimidazole or nitrotriazole to a solution of 1 and triflic acid in EtOH under $\mathrm{N}_{2}$ and then refluxing the mixture for 24 h . Corresponding reactions at r.t. showed $\left[\mathrm{Ru}(\mathrm{ma})_{2}(\mathrm{EtOH})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$ as the major species present in solution after 24 h , as analyzed by TLC. The elemental analyses for 15-17 were consistently high in $\mathrm{C}, \mathrm{H}$ and N and, as the ${ }^{1} \mathrm{H}$ NMR spectra of suspensions of $\mathbf{1 5}$ and 16 in $\mathrm{D}_{2} \mathrm{O}$ gave weak signals for free $2 \mathrm{NO}_{2} \mathrm{Im}$ and $4 \mathrm{NO}_{2} \mathrm{Im}$, respectively, some free ligand might be present in these complexes.

### 3.3.2 Solution ${ }^{1} \mathrm{H}$ NMR Spectroscopy of the Im, 2MeIm, 4MeIm and 1 MeIm Complexes

The ${ }^{1} \mathrm{H}$ NMR spectra of 6-10 were examined in $\mathrm{CDCl}_{3}$; the data for the structurally characterized complexes $\mathbf{8}$ and $\mathbf{1 0}$ are consistent with the primary isomer in solution being the trans-isomer (Table 3.3).

Table 3.3 ${ }^{1} \mathrm{H}$ NMR data of $\mathrm{Ru}(I I I)$ maltolato-imidazole complexes in $\mathrm{CDCl}_{3}$ at r.t.

a -signals for these protons were not observed.

For $\left[\mathrm{Ru}(\mathrm{ma})_{2}(1 \mathrm{MeIm})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}(8)$, the ma-Me resonance is shifted downfield to $\delta 62.6$ with respect to that of the Hma-Me ( $\delta 2.37$ ), and the Im-Me resonance at $\delta 13.41$ (Table 3.3) also shows a downfield shift with respect to that of free 1 MeIm ( $\delta 3.64$ ). The shift for the $\mathrm{Im}-\mathrm{Me}$ resonance is consistent with data for other $\mathrm{Ru}(I I I)$ - 1 MeIm complexes, ${ }^{5}$ and that for the ma-Me resonance is considered consistent with that observed for Ru (III)-ma (Table 3.1). The ${ }^{\mathrm{l}} \mathrm{H}$ NMR spectrum of $\mathbf{8}$ was first studied in acetone- $d_{6}$
(Figure 3.21a), following purification of the complex by preparative TLC: the data suggest the presence of a mixture of isomers. An in situ synthesis in $\mathrm{CD}_{3} \mathrm{OD}$ showed the formation of only the trans-isomer. When MeOH was used to extract the complex from the TLC plate, the ${ }^{1} \mathrm{H}$ NMR spectrum of the isolated solid in $\mathrm{CDCl}_{3}$ showed numerous peaks between $\delta 1-5$ that were not present in the ${ }^{1} \mathrm{H}$ NMR of the original crude mixture before purification; these can likely be assigned to the binder and other components of the TLC plate that may be soluble in MeOH . The workup procedure was then modified to use $1-2 \% \mathrm{MeOH}$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ to remove the complex from the silica scraped from the plate. The ${ }^{1} \mathrm{H}$ NMR spectrum of $\mathbf{8}$ was then recorded in $\mathrm{CDCl}_{3}$ and showed the transisomer in almost $100 \%$ purity (Figure 3.21b). Extraction of the other TLC-isolated imidazole complexes $(\mathbf{6}, 7,9,10,12$ and 13$)$ from the silica was subsequently performed using either neat $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ or a mixture of $\mathrm{MeOH}(<5 \%)$ and $\mathrm{CH}_{2} \mathrm{Cl}_{2}$.

Figure 3.21 ${ }^{\mathrm{I}} \mathrm{H}$ NMR spectrum of $\left[\mathrm{Ru}(\mathrm{ma})_{2}(1 \mathrm{MeIm})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}(\mathbf{8})$ in a) acetone- $d_{6}$ ( $300 \mathrm{MHz}, 298 \mathrm{~K}$ ) and b) $\mathrm{CDCl}_{3}(300 \mathrm{MHz}, 298 \mathrm{~K}$ ).

As discussed in Section 3.3.1, the complexes $\left[\mathrm{Ru}(\mathrm{ma})_{2}(\mathrm{~L})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$, where $\mathrm{L}=$ Im, 2 MeIm, 4 MeIm and 1 MeIm, were all synthesized via reactions at r.t. Heating the reaction mixtures led to the formation of numerous side-products. In the case of 1 MeIm
(Figure 3.22), at least 11 signals for the ma-Me group were observed in the ${ }^{1} \mathrm{H}$ NMR spectrum in $\mathrm{CDCl}_{3}$ of a solid isolated after a reaction mixture of 1 in EtOH with four equivalents of 1 MeIm and one equivalent of triflic acid had been refluxed for 6 h . Numerous additional signals were also observed in the regions where the imidazole methyl ( $\delta 21$ to 12 ) and $\mathrm{H}(5)$ ( $\delta 2$ to -8 ) proton resonances occur. After this reaction mixture was refluxed for $48 \mathrm{~h},\left[\mathrm{Ru}(\mathrm{ma})(1 \mathrm{MeIm})_{4}\right]\left[\mathrm{CF}_{3} \mathrm{SO}_{3}\right]_{2}(\boldsymbol{9})$ was isolated. The signal for the ma-Me of 9 ( $\delta 81.6$, Figure 3.23) is shifted farther downfield than for the bisimidazole complexes (Table 3.3). Two sharp resonances at $\delta 25.6$ and 20.4 , assigned as Im-Me groups, are shifted farther downfield than are those observed for the Im-Me groups of $8(\delta 13.4)$.

Figure 3.22 The effect of varying the temperature when reacting 1 with 1 MeIm. a) ${ }^{1} \mathrm{H}$ NMR spectrum in $\mathrm{CDCl}_{3}$ ( $300 \mathrm{MHz}, 298 \mathrm{~K}$ ) of the crude reaction mixture isolated after refluxing $\mathrm{Ru}(\mathrm{ma})_{3}$ with 4 equiv. of 1 MeIm and 1 equiv. of triflic acid in EtOH under $\mathrm{N}_{2}$ for 6 h . b) ${ }^{1} \mathrm{H}$ NMR spectrum $(300 \mathrm{MHz}, 298$ K ) of $\left[\mathrm{Ru}(\mathrm{ma})_{2}(1 \mathrm{MeIm})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}(\mathbf{8})$ in $\mathrm{CDCl}_{3}$.

Attempts to form similar tetrakis(imidazole) complexes with Im, 2MeIm, and 4MeIm were unsuccessful. Attempts to form a mixed tetrakis(imidazole) complex by refluxing 6 equivalents of 1 MeIm with one equivalent of $\left[\mathrm{Ru}(\mathrm{ma})_{2}(2 \mathrm{MeIm})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$ (10) and one equivalent of $\mathrm{CF}_{3} \mathrm{SO}_{3} \mathrm{H}$ in EtOH were also unsuccessful.

Figure 3.23 ${ }^{1} \mathrm{H}$ NMR spectrum ( $300 \mathrm{MHz}, 298 \mathrm{~K}$ ) of $\left[\mathrm{Ru}(\mathrm{ma})(1 \mathrm{MeIm})_{4}\right]\left[\mathrm{CF}_{3} \mathrm{SO}_{3}\right]_{2}(9)$ in acetone- $d_{6}$ showing the ma-Me at $\delta 81.6$ and $1 \mathrm{MeIm} \mathrm{H}(2)$ protons at $\delta$ -19.4 and -24.0. Two sharp resonances at $\delta 25.6$ and 20.4 are assigned as Im-Me groups.

The ${ }^{1} \mathrm{H}$ NMR spectrum of trans- $\left[\mathrm{Ru}(\mathrm{ma})_{2}(2 \mathrm{MeIm})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}(\mathbf{1 0})$ shows a single resonance at $\delta 67.0$ for the ma-Me groups (Figure 3.24); resonances for the $\mathrm{H}(4)(\delta-4.7)$, $\mathrm{H}(5)(\delta-1.6)$, and $\mathrm{Im}-\mathrm{Me}(\delta 42.0)$ protons are also observed.

Figure 3.24 ${ }^{1} \mathrm{H}$ NMR spectrum $(300 \mathrm{MHz}, 298 \mathrm{~K})$ of $\left[\mathrm{Ru}(\mathrm{ma})_{2}(2 \mathrm{MeIm})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}(\mathbf{1 0})$ in $\mathrm{CDCl}_{3}$.

The ${ }^{1} \mathrm{H}$ NMR spectrum of $\left[\mathrm{Ru}(\mathrm{ma})_{2}(4 \mathrm{MeIm})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$ (6) also shows only a single broad resonance for the ma-Me protons. Even though this complex has not been characterized crystallographically, it can be inferred from similarities between its ${ }^{1} \mathrm{H}$ NMR spectrum and those of trans-8 and trans-10, that $\mathbf{6}$ is also in a trans-configuration. The resonance for the Im-Me group is shifted less downfield for 6 ( $\delta 16.3$ ) than is observed for 10 ( $\delta 42.0$ ). In some $\mathrm{Ru}(I I I)$ complexes formed from 4MeIm, the 4MeIm isomerizes to 5 MeIm upon coordination, ${ }^{5}$ to relieve steric interactions between the Me group and other coordinated ligands. Anderson and Beauchamp have reported the ${ }^{1} \mathrm{H}$ NMR spectrum for the anion $\left[\mathrm{RuCl}_{4}(5 \mathrm{MeIm})_{2}\right]^{-}$in $\mathrm{D}_{2} \mathrm{O}$, attributing signals between $\delta$ -0.2 and 2.3 to the Me group of coordinated 5MeIm. ${ }^{5}$ Previous work in our group has described the chemical shifts of the Im-Me groups of a mixed 4-Me/5-Me Ru(III) cation, $\left[\mathrm{Ru}(\mathrm{acac})_{2}(4 \mathrm{MeIm})(5 \mathrm{MeIm})\right]^{+}$, assigning a signal for the $4-\mathrm{Me}$ group at $\delta 14.7$ and one for the $5-\mathrm{Me}$ group at $\delta 7.5 .{ }^{17}$ This suggests that $\left[\mathrm{Ru}(\mathrm{ma})_{2}(4 \mathrm{MeIm})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$ (6) likely exists as the $4-\mathrm{Me}$ species as its structure is analogous to that of the acac complex, and the chemical shift of the Im-Me falls close to that reported for the 4-Me group of the mixed-acac complex. It is difficult to determine if the chemical shift of the imidazole proton of 6 is definitive of either an $\mathrm{H}(4)$ or an $\mathrm{H}(5)$. Although the relative chemical shifts of the Im protons remain constant, $\mathrm{H}(5)<\mathrm{H}(4)<\mathrm{H}(2), \mathrm{H}(2)$ being the farthest upfield, the absolute regions in which these resonances are found varies considerably and are dependent on the nature of the other coordinated ligands. Steric interactions between the Im-Me and the ma ligands of $\mathbf{1 0}$ are overcome as the 2 MeIm tilts to move the Me away from the ma plane (Table 3.1, Section 3.3.1). The 4MeIm of 6 could tilt in a similar manner to remove steric interactions without isomerizing to 5MeIm. Without an X-ray structure, it is not possible to define this complex as the 4 MeIm species, but this would agree with the literature observations and the data collected for this complex.

The ${ }^{1} \mathrm{H}$ NMR spectrum of $\left[\mathrm{Ru}(\mathrm{ma})_{2}(\mathrm{Im})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$ (7) showed both the cis- and trans-isomers in solution, despite using the modified isolation technique that succeeded in removing the cis-isomers for $\mathbf{6}, \mathbf{8}$, and $\mathbf{1 0}$. Attempts to separate the two isomers of $\mathbf{7}$ by chromatography were unsuccessful. The intensities of the ${ }^{1} H$ NMR signals for the cisisomer varied between samples suggesting the absence of a solution equilibrium, and that two overlapping TLC bands may be the source of the two isomers. When silica taken
from the lower part of the red band was not included in the isolation, weaker signals for the cis-isomer were observed in the ${ }^{1} \mathrm{H}$ NMR spectrum, but the ${ }^{1} \mathrm{H}$ NMR spectrum taken from a sample isolated from a thin section ( $\sim 1 \mathrm{~mm}$ in width) cut from the top of the red band still revealed the presence of two isomers in solution.

Table 3.4 summarizes some ${ }^{1} \mathrm{H}$ NMR signals for trans$\left[\mathrm{Ru}(\mathrm{Ema})_{2}(4 \mathrm{MeIm})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$ (12) and trans-[Ru(Ema)$\left.)_{2}(2 \mathrm{MeIm})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$ (13), both synthesized from $\mathrm{Ru}(\mathrm{Ema})_{3}$, and the data for the corresponding ma complexes, $\mathbf{6}$ and $\mathbf{1 0}$; the chemical shifts for the Im-protons and -Me groups of $\mathbf{1 2}$ and $\mathbf{1 3}$ are almost identical to those of $\mathbf{6}$ and $\mathbf{1 0}$, respectively, while the Ema- $\mathrm{CH}_{2}$ resonances are shifted upfield from those of the ma-Me resonances for $\mathbf{6}$ and $\mathbf{1 0}$, respectively. As only one resonance is observed for the Ema- $\mathrm{CH}_{2}$ group, the Im-Me group, and each of the Im protons for both $\mathbf{1 2}$ and $\mathbf{1 3}$ (Figure 3.25), these complexes are likely trans-isomers. The chemical shift of the $\operatorname{Im}-\mathrm{Me}$ group for $\mathbf{1 2}$ is almost identical to that of $\mathbf{6}$, and therefore, by the same reasoning discussed previously in this Section for 6, 12 also likely exists as a 4MeIm complex and not a 5 MeIm one. The resonances for the Ema- $\mathrm{CH}_{2}-\mathrm{CH}_{3}$ is not observed and likely overlaps with the $\delta 0-10$ region in the spectrum where the solvent signals likely overwhelm any paramagnetic resonances.

Table 3.4 ${ }^{1} \mathrm{H}$ NMR data for the Ema-Im complexes 12 and 13, compared with those for the ma-Im complexes $\mathbf{6}$ and $\mathbf{1 0}$.

| Complex | $\delta$ Ema$\mathrm{CH}_{2}$ | $\begin{gathered} \delta \mathrm{ma} \\ \mathrm{CH}_{3} \\ \hline \end{gathered}$ | $\begin{aligned} & \hline \mathrm{\delta Im}- \\ & \mathrm{CH}_{3} \end{aligned}$ | $\begin{aligned} & \delta \mathrm{Im}- \\ & \mathrm{H}(5) \end{aligned}$ | $\begin{aligned} & \delta \mathrm{Im}- \\ & \mathrm{H}(4) \end{aligned}$ | $\begin{aligned} & \delta \mathrm{Im}- \\ & \mathrm{H}(2) \end{aligned}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| trans $-\left[\mathrm{Ru}(\mathrm{Ema})_{2}(4 \mathrm{MeIm})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}(\mathbf{1 2})$ | 49.1 | - | 16.5 | -4.6 | - | -19.0 |

Figure 3.25 ${ }^{1} \mathrm{H}$ NMR spectra ( $300 \mathrm{MHz}, 298 \mathrm{~K}$ ) of a) $\left[\mathrm{Ru}(\mathrm{Ema})_{2}(2 \mathrm{MeIm})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$ (13) in $\mathrm{CDCl}_{3}$ and b) $\left[\mathrm{Ru}(\mathrm{Ema})_{2}(4 \mathrm{MeIm})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$ (12) in $\mathrm{CDCl}_{3}$. The $\mathrm{H}(2)$ signal in (b) is very broad and can only be observed when the $y$-axis is expanded.

### 3.3.3 Solution ${ }^{1} \mathrm{H}$ NMR Spectroscopy of the metro, $2 \mathrm{NO}_{2} \mathbf{I m}, 4 \mathrm{NO}_{2} \mathbf{I m}$ and $\mathbf{3 N O} \mathbf{N O}_{2}$ tri Complexes

Of the complexes with metro (4,5, and 11), $2 \mathrm{NO}_{2} \operatorname{Im}(\mathbf{1 5}), 4 \mathrm{NO}_{2} \mathrm{Im}(16)$ and $3 \mathrm{NO}_{2}$ tri (17), only those with metro were soluble in aqueous solution. Unlike the ${ }^{1} \mathrm{H}$ NMR spectra for 6-10, $\mathbf{1 2}$ and 13, which were measured in $\mathrm{CDCl}_{3}$ (Section 3.3.2), the ${ }^{\mathrm{I}} \mathrm{H}$ NMR spectrum of $\left.\left[\mathrm{Ru}(\mathrm{ma})_{2} \text { (metro) }\right)_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$ (4) was measured in acetone- $d_{6}$ because of its insolubility in $\mathrm{CDCl}_{3}$; observed were a broad resonance for the ma-Me group ( $\delta 70.0$ ) and another for the Im-Me group ( $\delta 34.0$ ), consistent with a trans-geometry (as discussed in Section 3.3.2 for $\mathbf{6}, \mathbf{8}$ and 10) and the solid state structure. ${ }^{16}$

Similarly, in the ${ }^{1} \mathrm{H}$ NMR spectrum of $\left.\left[\mathrm{Ru}(\text { Ema })_{2} \text { (metro }\right)_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$ (11), broad signals for each of the ma-Me protons ( $\delta 65.3$ ), the Im-Me protons ( $\delta 32.2$ ), and the $\mathrm{H}(5)$ of metronidazole ( $\delta-4.8$ ) are consistent with the trans-geometry determined by X-ray crystallography (Section 3.3.1, Figure 3.20).

The ${ }^{1} \mathrm{H}$ NMR spectrum of $\left[\mathrm{Ru}(\mathrm{ma})_{2}(\right.$ metro $\left.)(\mathrm{EtOH})\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$ (5) in acetone- $d_{6}$ shows 4 signals in the region where the ma-Me group is typically observed. Five singlets between $\delta 21$ and 8 , which are not present in the spectrum for 4 , were also observed. These signals could be due to the $\mathrm{H}(5)$ or $\mathrm{H}(6)$ protons of ma, the metro-Me group, the metro 1-hydroxyethyl group, or bound EtOH ; signals for free EtOH were not observed even after 1 h showing that the acetone- $d_{6}$ was not displacing the coordinated EtOH.

The $\left[\mathrm{Ru}(\mathrm{ma})_{2}(\mathrm{~L})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$ complexes, where $\mathrm{L}=2 \mathrm{NO}_{2} \operatorname{Im}(15), 4 \mathrm{NO}_{2} \operatorname{Im}(16)$ and $3 \mathrm{NO}_{2}$ tri (17) were only readily soluble in dmso- $d_{6}$ for ${ }^{1} \mathrm{H}$ NMR investigation. For each of these three complexes, no paramagnetic signals were detected; however, intense signals were observed for the free heterocyclic ligands, implying that the complexes dissociate the ( N )-bound ligands in dmso- $d_{6}$. Weak signals were also observed for free ma, suggesting further decomposition of the complexes. The ${ }^{1} \mathrm{H}$ NMR spectrum of a suspension of 16 in acetone- $d_{6}$ was recorded ( 4096 scans over 2 h ) and a trace resonance was observed for the coordinated ma-Me group at $\delta 63.8$. Attempts to study $\mathbf{1 5}$ and $\mathbf{1 7}$ in a similar manner were unsuccessful. Further study of $15-17$ is needed to better understand their structures.

### 3.3.4 Compounds Synthesized Using 2,2,3,3,3-Pentafluoropropylamine (F5)

Three heterocyclic compounds were prepared via reaction with 2,2,3,3,3-pentafluoropropylamine (F5). An improved synthesis of EF5 (Figure 3.26) has been published

CIF5

Figure 3.26 Molecular structures of three compounds synthesized from F5.
by our group, ${ }^{18}$ but was further modified in this thesis work to limit the number of reagents required to convert F5 into EF5 and conserve the amount of F5 required because of the rapidly rising cost of this amine. In this work, F5 was purchased from Lancaster or Interchim or was prepared according to a published procedure (Figure 3.27). ${ }^{19,20}$

Figure 3.27 Synthesis of 2,2,3,3,3-pentrafluoropropylamine (F5) from 2, 2,3,3,3pentafluoroproprionic acid.

The procedure for synthesizing EF5 used chloroacetyl chloride to form the precursor N -(2,2,3,3,3-pentafluoropropyl)chloroacetamide (CIF5, Figure 3.26) instead of the previously used iodoacetic acid to form N -(2,2,3,3,3-pentafluoropropyl)iodoacetamide (IF5). ${ }^{18}$ The chloroacetyl chloride reaction proceeded more quickly and gave a higher yield ( 91 for ClF5 vs. $53 \%$ for IF5) than the corresponding reaction in which iodoacetic acid is first activated with isobutyl chloroformate before being reacted with F5. ${ }^{18}$ The reaction of CIF5 with $2 \mathrm{NO}_{2} \mathrm{Im}$ to afford EF5 proceeded identically to that reported for the corresponding reaction with IF5. ${ }^{18}$

The procedure used to prepare EF5 was also used to synthesize the new ligand 2-(3-nitro-1-H-triazol-1-yl)-N-(2,2,3,3,3-pentafluoropropyl)acetamide (triF5, Figure 3.26), but with use of $3 \mathrm{NO}_{2}$ tri instead of $2 \mathrm{NO}_{2} \mathrm{Im}$. Elemental analysis agreed with the formulation for triF5 that was further characterized by NMR and IR spectroscopies. A report investigating nitrotriazoles as potential anticancer agents ${ }^{10}$ led to the interest in developing this triazole analogue of EF5. Although complexes of this ligand were not tested for bioactivity in this work, preliminary biological results for triF5 itself will be discussed in Chapter 7.

The compound 1 H -imidazole-4,5-N,N'-bis(2,2,3,3,3-pentafluoropropyl)dicarboxamide, (IMF10, Figure 3.28), was synthesized by reacting imidazole-4,5dicarboxylic acid with two equivalents of isobutyl chloroformate and then adding two
equivalents of F5; IMF10 was characterized by MS and NMR spectroscopy. Elemental analysis indicates the presence of a $0.5 \mathrm{H}_{2} \mathrm{O}$ solvate. The two $\mathbb{R}$ bands between 3200 $3400 \mathrm{~cm}^{-1}$ presumably arise from $v(\mathrm{NH})$ and $v(\mathrm{OH})$.

Figure 3.28 Molecular structure of IMF10.

### 3.3.5 Synthesis, Characterization, and Solution ${ }^{1} \mathrm{H}$ NMR Spectroscopy of $\left[\mathrm{Ru}(\mathrm{ma})_{2}(\mathrm{EF} 5)_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3} \cdot \mathrm{EtOH}(14)$ and $\left[\mathrm{Ru}(\mathrm{ma})_{2}(\text { triF5 })_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$ (18)

Complexes 14 and 18 were synthesized from $\left[\mathrm{Ru}(\mathrm{ma})_{2}(\mathrm{EtOH})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$ (3) instead of $\mathrm{Ru}(\mathrm{ma})_{3}(\mathbf{1})$, because (in the absence of excess ma) this allowed for the use of stoichiometric amounts of EF5. The reactions proceeded quantitatively, and purification of the complexes was simpler than when using $\mathbf{1}$ as a precursor. $\mathbf{1 8}$ was insoluble in all solvents tested and thus was only characterized by IR spectroscopy and elemental analysis that agrees well with the proposed formulation. 14, on the other hand, was soluble in both EtOH and $\mathrm{H}_{2} \mathrm{O}$ and was therefore characterized by MS and NMR spectroscopy as well as IR spectroscopy and elemental analysis.

The ${ }^{1} \mathrm{H}$ NMR spectrum (r.t., $\mathrm{CD}_{3} \mathrm{OD}$ ) of $\left[\mathrm{Ru}(\mathrm{ma})_{2}(\mathrm{EF} 5)_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3} \cdot \mathrm{EtOH}$ (14) showed a broad resonance for the ma-Me group ( $\delta 59.2$ ) and two broad singlets at $\delta-4.8$ and -16.1 for the $\mathrm{H}(5)$ and $\mathrm{H}(4)$ protons, respectively. Resonances for the EF5 sidechain, and $\mathrm{H}(5)$ and $\mathrm{H}(6)$ of ma, are likely hidden in the $\delta 0-10$ region where trace signals for diamagnetic impurities and residual solvents overwhelm any 'paramagnetic' signals. Although the solid was dried for 24 h under vacuum at $78{ }^{\circ} \mathrm{C}$ before the ${ }^{\mathrm{l}} \mathrm{H}$ NMR spectrum was taken, signals for free EtOH are observed. The addition of one EtOH to the molecular formula fits well the elemental analysis. In the ${ }^{19} \mathrm{~F}$ NMR spectrum, two broad signals for the bound EF5 ( $\delta-8.9$ and -46.1 ) (Figure 3.29) overlap with a triplet ( $\delta-46.5$ )
and a multiplet ( $\delta-9.4$ ) that are for either free EF5 in solution or a diamagnetic impurity, although TLC analysis of the NMR sample showed no evidence of the free ligand. A singlet for the triflate counterion is also observed at $\delta-3.52$.

The mass spectrum gives peaks for $\left[\mathrm{M}^{+}-16\right]$ and $\left[\mathrm{M}^{+}-16-\mathrm{EF} 5\right]$, consistent with the commonly observed loss of an O -atom from a nitroaromatic group. ${ }^{21,22}$

Figure $3.29{ }^{19} \mathrm{~F}$ NMR spectrum ( $300 \mathrm{MHz}, 298 \mathrm{~K}$ ) of $\left[\mathrm{Ru}(\mathrm{ma})_{2}(\mathrm{EF} 5)_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3} \cdot \mathrm{EtOH}$ (14). Both signals for bound EF5 are broadened, while the sharper, diamagnetic signals likely correspond to those of free EF5.

### 3.4 Synthesis of $\left[\mathrm{Ru}(\mathrm{HMepyr})_{3}\right] \mathrm{Cl}_{3}(\mathbf{1 9 )}$

Preliminary attempts to synthesize a complex analogous to 1 but with 3-hydroxy-1,2-dimethyl-4-pyridone led instead to the synthesis of 19 that was characterized by $\mathbb{R}$ spectroscopy and the elemental analysis. The conductivity of an aqueous solution of $\mathbf{1 9}$ ( $451 \Omega^{-1} \mathrm{~cm}^{2} \mathrm{~mol}^{-1}$ ) is in the range for a $3: 1$ electrolyte. ${ }^{11}$ Attempts to deprotonate this complex and isolate a neutral species were unsuccessful.

### 3.5 Cyclic Voltammetry of Complexes

The $\mathrm{Ru}(I I I / I I)$ one-electron reduction potentials were determined for the complexes that were soluble in either MeCN or $\mathrm{CH}_{2} \mathrm{Cl}_{2}$. The potentials determined for $\mathrm{Ru}(\mathrm{ma})_{3}$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ agree with those reported in the literature, ${ }^{1}$ and those in MeCN are reported in Table 3.5. Of the mixed Im-ma complexes tested, $\mathbf{1 0}$ had the lowest reduction potential, and is also the most active ma complex from the MTT biological studies (Section 6.4.2). This observation counters the theory that to be biologically active, Ru (III) complexes should have a more positive reduction potential to facilitate in situ reduction to potentially more labile $\mathrm{Ru}(\mathrm{II})$ species. ${ }^{23}$ There does not appear, however, to be any direct link between the reduction potential and the in vitro activity, as will be discussed in more detail in Section 6.4.2.

Table 3.5 $\mathrm{Ru}(I I / I I)$ reduction potentials of ma and Ema-containing complexes.

| Complex | $\mathrm{Ru}(\mathrm{III} / \mathrm{II})$ Reduction Potential in <br> MeCN vs SCE (mV) |
| :--- | :---: |
| $\mathrm{Ru}(\mathrm{ma})_{3}(\mathbf{1})$ | -1132 |
| $\mathrm{Ru}(\mathrm{Ema})_{3}(\mathbf{2})$ | -1176 |
| $\left[\mathrm{Ru}(\mathrm{Ema})_{2}(2 \mathrm{MeIm})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}(\mathbf{1 3})$ | -889 |
| $\left[\mathrm{Ru}(\mathrm{Ema})_{2}(4 \mathrm{MeIm})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}(\mathbf{1 2})$ | -829 |

The $\mathrm{Ru}(\mathrm{III} / \mathrm{II})$ reduction potentials of the Ema complexes were some $14-90 \mathrm{mV}$ more negative than those for the corresponding ma complexes. 13, the complex with the lowest $\mathrm{IC}_{50}$ of all those tested for bioactivity (Section 6.4.2), had the lowest $\mathrm{Ru}(\mathrm{III} / \mathrm{II}$ ) reduction potential of the all the bis-imidazole complexes.

The voltammograms of the metro complexes were the only ones obtained for complexes with ligands containing a nitro group. With the exception of 14 , the other nitro containing complexes were insoluble in 0.100 M TBAP solutions in either $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ or MeCN . The CV of $\left.\left[\mathrm{Ru}(\mathrm{ma})_{2} \text { (metro }\right)_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$ (4) shows three reversible waves for $\mathrm{Ru}^{\text {IIIII }}(-554 \mathrm{mV}), \mathrm{Ru}^{\text {IV/III }}(1085 \mathrm{mV})$, and $\mathrm{NO}_{2} / \mathrm{NO}_{2}^{-}(-1111 \mathrm{mV})$ (Figure 3.30). Free metronidazole was found to undergo a 1 -electron reduction for the nitro group at -1154 $\mathrm{mV}, 43 \mathrm{mV}$ more negative than for the coordinated ligand, and 17 mV more negative than for $\left.\left[\mathrm{Ru}(\mathrm{Ema})_{2} \text { (metro) }\right)_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}(11)\left(\mathrm{E}_{1 / 2} \quad\left(\mathrm{NO}_{2} / \mathrm{NO}_{2}{ }^{-}\right)=-1137 \mathrm{mV}\right)$. From these data it can be concluded (as expected) that coordination of metronidazole to Ru (III) makes the reduction of the nitro group easier (i.e. gives a more positive potential). 14 was soluble in MeCN but no signals were observed in the voltammogram between -2 and 2 V .

Figure 3.30 Cyclic voltammogram of $\left[\mathrm{Ru}(\text { metro })_{2}(\mathrm{ma})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$ (4) in MeCN containing ferrocene.

### 3.6 Experimental Procedures for the Syntheses of Compounds Derived from F5

### 3.6.1 N -(2,2,3,3,3-pentafluoropropyl)chloroacetamide (CIF5)

This compound was prepared via a modified reported procedure. ${ }^{17}$ Chloroacetyl chloride ( $0.375 \mathrm{~mL}, 4.71 \mathrm{mmol}$ ) was dissolved in THF at $0{ }^{\circ} \mathrm{C}$ under $\mathrm{N}_{2}$. To this solution was added 2,2,3,3,3-pentafluoropropylamine (F5) ( $0.500 \mathrm{~mL}, 4.70 \mathrm{mmol}$ ) and N methylmorpholine (NMM) $(0.410 \mathrm{~mL}, 4.70 \mathrm{mmol})$. The mixture was stirred at $0{ }^{\circ} \mathrm{C}$ for 30 min , at which time the ice-bath was removed and stirring was continued for an additional 30 min . The solution was filtered to remove a white precipitate and the filtrate was then evaporated under vacuum to leave a yellow, crystalline solid. This solid was dried under vacuum at $0{ }^{\circ} \mathrm{C}$ for 24 h . Yield: 0.96 g ( $91 \%$ ). ${ }^{1} \mathrm{H}$ NMR (acetone- $d_{6}$ ): $\delta 8.16(\mathrm{~s}, 1 \mathrm{H}, \mathrm{NH}) ; 4.26\left(\mathrm{~s}, 2 \mathrm{H}, \mathrm{ClCH}_{2}\right) ; 4.15\left(\mathrm{td}, 2 \mathrm{H} \mathrm{CH}_{2} \mathrm{CF}_{2}\right) .{ }^{19} \mathrm{~F}\left\{{ }^{1} \mathrm{H}\right\}$ NMR (acetone$\left.d_{6}\right): \delta-8.25\left(\mathrm{t}, \mathrm{C} F_{3}\right) ;-45.27\left(\mathrm{q}, \mathrm{C} F_{2}\right)$. IR (KBr pellet): v $3320(\mathrm{~N}-\mathrm{H}, \mathrm{m}), 1655(\mathrm{C}=\mathrm{O}, \mathrm{s})$. ESI-MS (MeOH): $190\left(\mathrm{M}^{+}-\mathrm{Cl}\right)$. The spectroscopic data agree with those previously reported. ${ }^{17}$

### 3.6.2 2-(2-Nitro-1-H-imidazol-1-yl)-N-(2,2,3,3,3-pentafluoropropyl)acetamide (EF5)

This ligand was synthesized using a modified procedure from that published by Baird et al. ${ }^{18}$ A solution of $2 \mathrm{NO}_{2} \operatorname{Im}(0.10 \mathrm{~g}, 0.92 \mathrm{mmol})$ in DMF ( 5 mL ) was degassed with $\mathrm{N}_{2}$ for 10 min . To this solution was added $\mathrm{Cs}_{2} \mathrm{CO}_{3}(0.30 \mathrm{~g}, 0.93 \mathrm{mmol})$. Stirring of this mixture at $50^{\circ} \mathrm{C}$ for 2 h yielded a yellow solution and a white precipitate. To this mixture was added CIF5, and the reaction mixture was then stirred for 3 h at $50{ }^{\circ} \mathrm{C}$. The solution was filtered and the precipitate washed with dry THF ( $3 \times 5 \mathrm{~mL}$ ). The filtrate was reduced in volume to 1 mL and then loaded onto a silica gel column. Elution of the column $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right.$ :acetone, $\left.10: 1\right)$ removed unreacted starting materials. The concentration of acetone was then increased to $40 \%$ to elute EF5. The fractions containing the product were combined and evaporated under vacuum to yield EF5 as a white solid. Yield: 0.23 g (82\%). ${ }^{1} \mathrm{H}$ NMR ( $\mathrm{CD}_{3} \mathrm{OD}$ ): $\delta 7.48\left(\mathrm{~s}, 1 \mathrm{H}, \mathrm{Im}-H_{5}\right) ; 7.21$ ( $\left.\mathrm{s}, 1 \mathrm{H}, \operatorname{Im}-H_{4}\right) ; 5.29(\mathrm{~s}, 2 \mathrm{H}$ $\mathrm{CH}_{2} \mathrm{CO}$ ); 4.08 (t, $2 \mathrm{H} \mathrm{CH}_{2} \mathrm{CF}_{2}$ ). ${ }^{19} \mathrm{~F}\left\{{ }^{1} \mathrm{H}\right\} \operatorname{NMR}\left(\mathrm{CD}_{3} \mathrm{OD}\right): \delta-10.58\left(\mathrm{t}, \mathrm{CF}_{3}\right) ;-47.21$ ( q , $\mathrm{C} F_{2}$ ). IR (KBr pellet): v $3305(\mathrm{~N}-\mathrm{H}, \mathrm{m}), 1686(\mathrm{C}=\mathrm{O}, \mathrm{s}), 1490\left(\mathrm{~N}-\mathrm{O}_{\text {asym }}, \mathrm{m}\right), 1363(\mathrm{~N}-$ $\mathrm{O}_{\text {sym }}$, s). ESI-MS (MeOH): $303\left(\mathrm{M}^{+}\right)$. Anal. Calcd for $\mathrm{C}_{8} \mathrm{H}_{7} \mathrm{~N}_{4} \mathrm{O}_{3} \mathrm{~F}_{5}: \mathrm{C}, 31.80$; H, 2.34;
$\mathrm{N}, 18.54$. Found: $\mathrm{C}, 31.62 ; \mathrm{H}, 2.44 ; \mathrm{N}, 18.25$. The data agree with those reported in the literature. ${ }^{18}$

### 3.6.3 2-(3-Nitro-1-H-triazol-1-yl)-N-(2,2,3,3,3-pentafluoropropyl)acetamide (triF5)

This compound was prepared using the same procedure as that for EF5, but using 3-nitro-1,2,4-triazole ( $0.048 \mathrm{~g}, 0.42 \mathrm{mmol}$ ) in place of $2 \mathrm{NO}_{2} \mathrm{Im}$, and $\mathrm{Cs}_{2} \mathrm{CO}_{3}(0.14 \mathrm{~g}, 0.43$ $\mathrm{mmol})$. The triF5 product was isolated as a pale yellow solid. Yield: $0.86 \mathrm{~g}(67 \%) .{ }^{\mathrm{t}} \mathrm{H}$ NMR (aceton- $d_{6}$ ): $\delta 8.61$ ( $\mathrm{s}, 1 \mathrm{H}$, tri- $\mathrm{H}_{5}$ ); 8.17 ( $\mathrm{s}, 1 \mathrm{H} \mathrm{N}-\mathrm{H}$ ); 5.24 ( $\mathrm{s}, 2 \mathrm{H}-\mathrm{CH}_{2}-\mathrm{CO}-$ ); 4.11 $\left(\mathrm{td}, 2 \mathrm{H}-\mathrm{CH}_{2}-\mathrm{CF}_{2}-\right) .{ }^{19} \mathrm{~F}\left\{{ }^{1} \mathrm{H}\right\}$ NMR (acetone- $d_{6}$ ): $\delta-10.41\left(\mathrm{t},-\mathrm{C} F_{3}\right) ;-48.65\left(\mathrm{q},-\mathrm{C} F_{2}-\right)$. IR (KBr pellet): v $3341(\mathrm{~N}-\mathrm{H}, \mathrm{m}), 1701(\mathrm{C}=\mathrm{O}, \mathrm{s}), 1407\left(\mathrm{~N}-\mathrm{O}_{\text {asym }}, \mathrm{m}\right), 1318\left(\mathrm{~N}-\mathrm{O}_{\text {sym }}, \mathrm{s}\right)$. ESIMS (MeOH): $304\left(\mathrm{M}^{+}\right)$. Anal. Calcd for $\mathrm{C}_{7} \mathrm{H}_{6} \mathrm{~N}_{5} \mathrm{O}_{3} \mathrm{~F}_{5}: \mathrm{C}, 27.72 ; \mathrm{H}, 1.98 ; \mathrm{N}, 23.10$. Found: C, 27.62; H, 2.14; N, 22.87.

### 3.6.4 IMF10

To a suspension of imidazole-4,5,-dicarboxylic acid ( $0.10 \mathrm{~g}, 0.65 \mathrm{mmol}$ ) in THF $(5 \mathrm{~mL})$ under an atmosphere of $\mathrm{N}_{2}$ was added NMM ( $0.115 \mathrm{~mL}, 1.32 \mathrm{mmol}$ ). The mixture was stirred for 10 min at which time isobutyl chloroformate was added ( 0.175 $\mathrm{mL}, 1.34 \mathrm{mmol}$ ). The mixture was stirred at r.t. for 1 h . Pentafluoropropyl amine ( 0.140 $\mathrm{mL}, 1.31 \mathrm{mmol}$ ) was then added and the mixture stirred under $\mathrm{N}_{2}$ for 12 h at r.t. The mixture was then filtered to remove the white precipitate and the yellow filtrate was collected, and evaporated to leave a yellow oil. TLC analysis $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}: \mathrm{MeOH}, 10: 1\right)$ showed a single major product, $\mathrm{R}_{\mathrm{f}}=0.67$. The oil was purified using column chromatography $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}: \mathrm{MeOH}, 10: 1\right)$ and the combined fractions for this band were collected and evaporated under vacuum to yield a yellow solid. Yield $0.086 \mathrm{~g}(31 \%)$. ${ }^{1} \mathrm{H} \operatorname{NMR}\left(\mathrm{CD}_{3} \mathrm{OD}\right): \delta 7.72$ (s, 1H, Im- $\mathrm{H}_{2}$ ); 4.12 (td, $4 \mathrm{H}-\mathrm{CH}_{2}-\mathrm{CF}_{2}$ ). ${ }^{19} \mathrm{~F}\left\{{ }^{1} \mathrm{H}\right\}$ NMR (acetone- $d_{6}$ ): $\delta-8.20\left(\mathrm{t},-\mathrm{C} F_{3}\right.$ ); -45.07 (q, -C $F_{2}$ ). IR (KBr pellet): v $3322(\mathrm{~N}-\mathrm{H}, \mathrm{m}), 3226$ ( $\mathrm{N}-\mathrm{H}, \mathrm{br} \mathrm{s}$ ), 1648 ( $\mathrm{C}=\mathrm{O}, \mathrm{s}$ ). LR-MS (+LSIMS, thioglycerol): $418\left(\mathrm{M}^{+}\right)$. Anal. Calcd for $\mathrm{C}_{11} \mathrm{H}_{8} \mathrm{~N}_{4} \mathrm{O}_{2} \mathrm{~F}_{10} \cdot 0.5 \mathrm{H}_{2} \mathrm{O}: \mathrm{C}, 30.91 ; \mathrm{H}, 2.11$; N, 13.11. Found: C, 30.86; H, 2.31; N, 12.47.

### 3.7 Experimental Procedures for the Syntheses of Ru(III) Complexes

### 3.7.1 $\mathrm{Ru}(\mathrm{ma})_{3} \mathbf{( 1 )}$

This compound was synthesized by a literature procedure. ${ }^{1}$ To a brown solution of $\mathrm{RuCl}_{3} \cdot 3 \mathrm{H}_{2} \mathrm{O}(1.01 \mathrm{~g}, 3.86 \mathrm{mmol})$ in water $(80 \mathrm{~mL})$ and sodium acetate $(4.0 \mathrm{~g}, 30$ $\mathrm{mmol})$, maltol was added $(2.50 \mathrm{~g}, 19.2 \mathrm{mmol})$ under $\mathrm{N}_{2}$, and the mixture refluxed for 6 h ; a red precipitate was then collected by filtration. TLC analysis $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}: \mathrm{MeOH}, 20: 1\right)$ revealed two spots; the product $\left(\mathrm{R}_{\mathrm{f}}=0.6\right)$ and an impurity $\left(\mathrm{R}_{\mathrm{f}}=0\right)$. The mixture was then dissolved in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(40 \mathrm{~mL})$ and filtered through Celite ( 2 g ) to remove the black impurity. The filtrate was reduced in volume to $\sim 5 \mathrm{~mL}$ at which time hexanes ( 30 mL ) were added to yield a red precipitate. The product was isolated via filtration and dried at $78{ }^{\circ} \mathrm{C}$ under vacuum for 48 h . Yield: $0.95 \mathrm{~g}(52 \%) .{ }^{1} \mathrm{H} \mathrm{NMR}\left(\mathrm{CD}_{2} \mathrm{Cl}_{2}\right): \delta 43.2,41.0$, 21.1 (s, $-\mathrm{CH}_{3}$ ); 11.8 (s, $H_{5}-\mathrm{ma}$ ), 9.2 ( $\mathrm{s}, H_{6}-\mathrm{ma}$ ); 3.1 ( $\mathrm{s}, H_{6}-\mathrm{ma}$ ), -4.6 (s, $H_{5}-\mathrm{ma}$ ); 0.8 (s, $H_{6^{-}}$ $\mathrm{ma}),-0.9\left(\mathrm{~s}, H_{5}-\mathrm{ma}\right)$. IR (KBr pellet): v $1600(\mathrm{C}=\mathrm{O}, \mathrm{s}), 1551(\mathrm{~s}), 1466(\mathrm{~s}), 1261$ ( s$), 1199$ (s). LR-MS (+LSIMS, thioglycerol): $477\left(\mathrm{M}^{+}\right), 352\left(\mathrm{M}^{+}-\mathrm{ma}\right)$. UV-vis $\left(\mathrm{H}_{2} \mathrm{O}\right): 216$ (45.4), 284 (14.1), 380 (10.2). $\quad \mathrm{CV}(\mathrm{MeCN}): \mathrm{E}_{1 / 2}\left(\mathrm{Ru}^{\text {IIIIII }}\right)=-1.132 \mathrm{~V}, \mathrm{E}_{1 / 2}\left(\mathrm{Ru}^{\mathrm{IV} / \mathrm{III}}\right)=$ 0.524 V vs. SCE. $\mathrm{CV}\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right): \mathrm{E}_{1 / 2}\left(\mathrm{Ru}^{\text {II/II }}\right)=-1.273 \mathrm{~V}, \mathrm{E}_{1 / 2}\left(\mathrm{Ru}^{\mathrm{IV} / I I I}\right)=0.497 \mathrm{~V}$ vs. SCE. $\quad \Lambda_{M}\left(\mathrm{H}_{2} \mathrm{O}\right)=25 . \Omega^{-1} \mathrm{~cm}^{2} \mathrm{~mol}^{-1}$. Anal. Calcd for $\mathrm{C}_{18} \mathrm{H}_{15} \mathrm{O}_{9} \mathrm{Ru}: \mathrm{C}, 45.38 ; \mathrm{H}, 3.17$. Found: $\mathrm{C}, 45.32 ; \mathrm{H}, 3.19$. The CV (in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ ) and IR data agree with those reported in the literature ${ }^{1}$ The X -ray structure shows a mer-configuration (Section 3.2.1).

### 3.7.2 $\mathrm{Ru}(\mathrm{Ema})_{3}(2)$

This complex was synthesized following the procedure outlined in Section 3.6.1, but using ethylmaltol in lieu of maltol $(2.80 \mathrm{~g}, 20 \mathrm{mmol})$. TLC analysis $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}: \mathrm{MeOH}\right.$, $20: 1$ ) revealed two spots; the product $\left(\mathrm{R}_{\mathrm{f}}=0.55\right)$ and an impurity $\left(\mathrm{R}_{\mathrm{f}}=0\right)$. The mixture was then dissolved in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(50 \mathrm{~mL})$ and filtered through Celite ( 3 g ) to remove the impurity. The filtered solution was reduced in volume to $\sim 5 \mathrm{~mL}$ at which time hexanes $(20 \mathrm{~mL})$ were slowly added to yield a red precipitate. The precipitate was collected, and dried at $78{ }^{\circ} \mathrm{C}$ under vacuum for 48 h . Yield: $0.83 \mathrm{~g}(45 \%) .{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CD}_{2} \mathrm{Cl}_{2}\right): \delta 40.1$, $38.8,35.3,33.4,21.7,18.9\left(\mathrm{~s},-\mathrm{CH}_{2} \mathrm{CH}_{3}\right) ; 4.9,4.8,2.1\left(\mathrm{~s},-\mathrm{CH}_{2} \mathrm{CH}_{3}\right) ; 12.5\left(\mathrm{H}_{5}-\mathrm{Ema}\right), 9.0$ ( $H_{6}$-Ema); $4.9\left(H_{6}\right.$-Ema), $-4.9\left(H_{5}\right.$-Ema); $1.2\left(H_{6}\right.$-Ema), $-0.8\left(H_{5}\right.$-Ema). IR (KBr pellet): $v$

1596 (C=O, s), 1550 (s), 1471 (s), 1258 (s), 1187 (s). LR-MS (+LSIMS, thioglycerol): $519\left(\mathrm{M}^{+}\right), 380\left(\mathrm{M}^{+}\right.$- Ema). UV-vis $\left(\mathrm{H}_{2} \mathrm{O}\right): 216$ (45.1), 284 (14.4), 382 (10.6). CV $(\mathrm{MeCN}): \mathrm{E}_{1 / 2}\left(\mathrm{Ru}^{\text {IIIII }}\right)=-1.176 \mathrm{~V}, \mathrm{E}_{1 / 2}\left(\mathrm{Ru}^{\text {IV/III }}\right)=0.540 \mathrm{~V}$ vs. SCE. $\mathrm{CV}\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right): \mathrm{E}_{1 / 2}$ $\left(\mathrm{Ru}^{\text {IIIII }}\right)=-1.292 \mathrm{~V}, \mathrm{E}_{1 / 2}\left(\mathrm{Ru}^{\text {IV/III }}\right)=0.493 \mathrm{~V}$ ys. SCE. $\Lambda_{\mathrm{M}}\left(\mathrm{H}_{2} \mathrm{O}\right)=36 \Omega^{-1} \mathrm{~cm}^{2} \mathrm{~mol}^{-1}$. Anal. Calcd for $\mathrm{C}_{21} \mathrm{H}_{21} \mathrm{O}_{9} \mathrm{Ru}: \mathrm{C}, 48.65$; H, 4.08. Found: C, $48.64 ; \mathrm{H}, 4.09$.

### 3.7.3 $\left[\mathrm{Ru}(\mathrm{ma})_{2}(\mathrm{EtOH})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$ (3)

To a red solution of $1(0.090 \mathrm{~g}, 0.19 \mathrm{mmol})$ in $\mathrm{EtOH}(5 \mathrm{~mL})$, triflic acid was added $(0.030 \mathrm{~g}, 0.20 \mathrm{mmol})$ under $\mathrm{N}_{2}$ and the solution refluxed for 1 h . The solvent was reduced to $\sim 1 \mathrm{~mL}$ under vacuum to which $\mathrm{Et}_{2} \mathrm{O}(20 \mathrm{~mL})$ was added. A red precipitate, which contained only one band by TLC analysis $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}: \mathrm{MeOH}, 20: 1 ; \mathrm{R}_{\mathrm{f}}=0.45\right)$, was collected and washed with $\mathrm{Et}_{2} \mathrm{O}(2 \times 5 \mathrm{~mL})$ before being dried at r.t. under vacuum for 24 h. Yield: $0.048 \mathrm{~g}(43 \%) .{ }^{\mathrm{I}} \mathrm{H} \operatorname{NMR}\left(\mathrm{CD}_{3} \mathrm{OD}\right): \delta 48.0$ (br s, $\mathrm{CH}_{3}$-ma); 28.0, 26.0 (br s, $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}$ ). IR (KBr pellet): v 3427 ( $\mathrm{O}-\mathrm{H}, \mathrm{m}$ ), $1608(\mathrm{C}=\mathrm{O}, \mathrm{s}), 1471$ ( s ), 1261 (s). LRMS (+LSIMS, thioglycerol): $444\left(\mathrm{M}^{+}\right), 398\left(\mathrm{M}^{+}-\mathrm{EtOH}\right), 352\left(\mathrm{M}^{+}-2 \mathrm{EtOH}\right) . \Lambda_{\mathrm{M}}(\mathrm{EtOH})$ $=36 \Omega^{-1} \mathrm{~cm}^{2} \mathrm{~mol}^{-1}$. Anal. Calcd for $\mathrm{C}_{17} \mathrm{H}_{22} \mathrm{~F}_{3} \mathrm{O}_{11} \mathrm{Ru}: \mathrm{C}, 34.46$; H, 3.72. Found: C, 34.53; H, 3.75.

### 3.7.4 $\left[\mathrm{Ru}(\mathrm{ma})_{2}(\text { metro })_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}(4)$ and $\left[\mathrm{Ru}(\mathrm{ma})_{2}(\right.$ metro $\left.)(\mathrm{EtOH})\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$ (5)

To a red solution of $1(0.090 \mathrm{~g}, 0.19 \mathrm{mmol})$ in $\mathrm{EtOH}(5 \mathrm{~mL})$, triflic acid was added $(0.030 \mathrm{~g}, 0.20 \mathrm{mmol})$ under $\mathrm{N}_{2}$ and the solution was refluxed for 1 h . Metronidazole was then added $(0.13 \mathrm{~g}, 0.76 \mathrm{mmol})$ and the solution was refluxed for an additional 6 h . After 2 h the solution was green and slowly turned blue over the next 4 h . The solvent was removed under vacuum and $\mathrm{CH}_{2} \mathrm{Cl}_{2}(10 \mathrm{~mL})$ was added. The mixture was shaken vigorously to leave a blue solid suspended in a green solution. The solid (4) was removed by filtration and washed with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(2 \times 5 \mathrm{~mL})$ before being dried at 78 ${ }^{\circ} \mathrm{C}$ under vacuum for 48 h . Yield: $0.080 \mathrm{~g}(50 \%) .{ }^{1} \mathrm{H}$ NMR (acetone $-d_{6}$ ): $\delta 70.0$ (br s, $\mathrm{CH}_{3}$-ma); 34.0 (br s, $\mathrm{CH}_{3}$-metro); -6.3 (br s, $\mathrm{H}_{5}$-metro). IR ( KBr pellet): v 3420 ( $\mathrm{O}-\mathrm{H}$, $\mathrm{m}), 1604(\mathrm{C}=\mathrm{O}, \mathrm{s}), 1561\left(\mathrm{~N}^{2} \mathrm{O}_{\text {asym }}, \mathrm{m}\right), 1367\left(\mathrm{~N}^{2} \mathrm{O}_{\text {sym }}, \mathrm{m}\right), 1446$ (s), 1263 (s). LR-MS (+LSIMS, thioglycerol): $694\left(\mathrm{M}^{+}\right), 523\left(\mathrm{M}^{+}\right.$- metro), $352\left(\mathrm{M}^{+}-2\right.$ metro). CV (MeCN): $\mathrm{E}_{1 / 2}\left(\mathrm{NO}_{2} / \mathrm{NO}_{2}^{-}\right)=-1.111 \mathrm{~V}, \mathrm{E}_{1 / 2}\left(\mathrm{Ru}^{\mathrm{III/II}}\right)=-0.554 \mathrm{~V}, \mathrm{E}_{1 / 2}\left(\mathrm{Ru}^{\mathrm{IV} / I I \mathrm{I}}\right)=1.085 \mathrm{~V}$ vs. SCE.

Anal. Calcd for $\mathrm{C}_{25} \mathrm{H}_{28} \mathrm{~F}_{3} \mathrm{~N}_{6} \mathrm{O}_{15} \mathrm{SRu}$ (4): C, 35.63; H, 3.33; N, 9.98. Found: C, 35.68; H, 3.41; N, 9.76.

After 4 was removed by filtration, the green solution was reduced in volume to $\sim 2$ mL and mounted on a $20 \times 20 \mathrm{~cm}$ silica preparative TLC plate. The plate was developed with $\mathrm{CH}_{2} \mathrm{Cl}_{2}: \mathrm{MeOH}, 25: 1(130 \mathrm{~mL})$. A green band was cut from the silica plate, suspended in 20 mL of a solution of $\mathrm{CH}_{2} \mathrm{Cl}_{2}: \mathrm{EtOH}, 19: 1$, and the mixture was left stirring for 16 h . The green mixture was then filtered to remove the silica and the solvent was removed under vacuum. The green oil remaining was dissolved in $\sim 3 \mathrm{mLCH}_{2} \mathrm{Cl}_{2}$ and hexanes $(10 \mathrm{~mL})$ were then added. The resulting green product was collected, washed with hexanes ( $2 \times 5 \mathrm{~mL}$ ) and dried at $78^{\circ} \mathrm{C}$ under vacuum for 24 h . Yield: $0.032 \mathrm{~g}(12$ $\%$ ). ' ${ }^{1} \mathrm{H}$ NMR (acetone- $d_{6}$ ): $\delta 70.4,65.6,61.7,54.2$ (br s, $\mathrm{CH}_{3}$-ma); 41.3, 34.9 (br s, $\mathrm{CH}_{3}$ metro); 24.97, 20.99, 19.01 (br s, $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}$ ); -3.13, -6.29 (br s, metro- $\mathrm{H}_{5}$ ). IR ( KBr
 1263 (s). LR-MS (+LSIMS, thioglycerol): $523\left(\mathrm{M}^{+}-\mathrm{EtOH}\right), 352\left(\mathrm{M}^{+}-\mathrm{EtOH}\right.$ - metro). $\mathrm{CV}(\mathrm{MeCN}): \mathrm{E}_{1 / 2}\left(\mathrm{Ru}^{\text {IIIII }}\right)=-0.496 \mathrm{~V}$. Anal. Calcd for $\mathrm{C}_{21} \mathrm{H}_{25} \mathrm{~F}_{3} \mathrm{~N}_{3} \mathrm{O}_{13} \mathrm{SRu}(5): \mathrm{C}, 35.15$; H, 3.49; N, 5.86. Found: C, 34.87; H, 3.32; N, 6.09.

### 3.7.5 $\left[\mathrm{Ru}(\mathrm{ma})_{2}(4 \mathrm{MeIm})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3} \cdot \mathrm{CH}_{2} \mathrm{Cl}_{\mathbf{2}}(\mathbf{6})$

To a red solution of $1(0.050 \mathrm{~g}, 0.11 \mathrm{mmol})$ in $\mathrm{EtOH}(5 \mathrm{~mL})$, triflic acid was added $(0.020 \mathrm{~g}, 0.13 \mathrm{mmol})$ under $\mathrm{N}_{2}$ and the solution stirred at r.t. for 1 h . After 1 h , 4MeIm was added $(0.041 \mathrm{~g}, 0.50 \mathrm{mmol})$ and the solution was stirred for an additional 12 h. After 4 h the solution was checked by TLC $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}: \mathrm{MeOH}, 10: 1\right)$. The band for complex 5 had disappeared and been replaced by 3 major red. bands $\left(\mathrm{R}_{\mathrm{f}}=0.32,0.44\right.$, $0.54)$. After 12 h , only one major red band was observed by $\operatorname{TLC}\left(\mathrm{R}_{\mathrm{f}}=0.56\right)$. The solvent was removed under vacuum and the dark red residue was dissolved in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ (2 mL ) and mounted on a $20 \times 20 \mathrm{~cm}$ silica preparative TLC plate that was developed with $\mathrm{CH}_{2} \mathrm{Cl}_{2}: \mathrm{MeOH}, 20: 1(130 \mathrm{~mL})$, when one major red band observed. This red band was cut out, added to 50 mL of $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, and the mixture was left stirring for 16 h . This was then filtered to remove the silica and the volume was reduced to $\sim 5 \mathrm{~mL}$. Hexanes ( 30 mL ) were then added and the resulting red precipitate was collected, washed with
hexanes ( $2 \times 5 \mathrm{~mL}$ ) and dried at $78{ }^{\circ} \mathrm{C}$ under vacuum for 48 h . Yield: $0.032 \mathrm{~g}(42 \%) .{ }^{1} \mathrm{H}$ NMR ( $\mathrm{CDCl}_{3}$ ): $\delta 60.0$ (br s, $\mathrm{CH}_{3}$-ma); 16.3 (br s, $\mathrm{CH}_{3}$-Im); -4.5 (br s, $H_{5}$-Im); -20.0 (br s, $H_{2}$-Im). IR (KBr pellet): v 3224 (N-H, m), 1601 ( $\mathrm{C}=\mathrm{O}, \mathrm{s}$ ), 1446 (s), 1263 (s). LR-MS (+LSIMS, thioglycerol): $516\left(\mathrm{M}^{+}\right), 434\left(\mathrm{M}^{+}-4 \mathrm{MeIm}\right), 352\left(\mathrm{M}^{+}-2(4 \mathrm{MeIm})\right) . \mathrm{CV}$ $(\mathrm{MeCN}): \mathrm{E}_{1 / 2}\left(\mathrm{Ru}^{\text {IIIIII }}\right)=-0.738 \mathrm{~V} . \Lambda_{\mathrm{M}}(\mathrm{MeOH})=107 \Omega^{-1} \mathrm{~cm}^{2} \mathrm{~mol}^{-1}$. Anal. Calcd for $\mathrm{C}_{21} \mathrm{H}_{22} \mathrm{~F}_{3} \mathrm{~N}_{4} \mathrm{O}_{9} \mathrm{SRu} \cdot \mathrm{CH}_{2} \mathrm{Cl}_{2}$ : C, 35.25; H, 3.20; N, 7.48. Found: C, 35.63; H, 3.26; N, 7.55.

### 3.7.6 $\left[\mathrm{Ru}(\mathrm{ma})_{2}(\mathrm{Im})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$ (7)

To a red solution of $1(0.055 \mathrm{~g}, 0.12 \mathrm{mmol})$ in $\mathrm{EtOH}(5 \mathrm{~mL})$, triflic acid was added $(0.022 \mathrm{~g}, 0.14 \mathrm{mmol})$ under $\mathrm{N}_{2}$ and the solution stirred at r.t. for 1 h . After 1 h , Im was added $(0.035 \mathrm{~g}, 0.51 \mathrm{mmol})$ and the solution was stirred for an additional 12 h . After 4 h the solution was checked by TLC $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}: \mathrm{MeOH}, 10: 1\right)$. The band for complex 5 had disappeared and been replaced by 11 minor bands. After 12 h , a single major band was observed with 5 minor bands of lower $R_{f}$. The solvent was removed under vacuum and the dark red residue was dissolved in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(2 \mathrm{~mL})$ and mounted on a $20 \times 20 \mathrm{~cm}$ silica preparative TLC plate that plate was developed with $\mathrm{CH}_{2} \mathrm{Cl}_{2}: \mathrm{MeOH}, 15: 1$ (130 mL ). When the major band had clearly separated, it was cut from the silica plate, and added to 50 mL of $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ with 1 mL MeOH ; this mixture was left stirring for 16 h . The red mixture was then filtered to remove the silica and the filtrate was reduced in volume to $\sim 5 \mathrm{~mL}$. Hexanes ( 30 mL ) were then added and the resulting red precipitate was collected, washed with hexanes ( $2 \times 5 \mathrm{~mL}$ ) and dried at $78{ }^{\circ} \mathrm{C}$ under vacuum for 48 h . Yield: $0.038 \mathrm{~g}(51 \%) .{ }^{1} \mathrm{H}$ NMR (cis-isomer, $\mathrm{CDCl}_{3}$ ): $\delta 62.2,44.6$ (s, $\mathrm{CH}_{3}$-ma); -1.5. -5.6 (s, $H_{5}$-Im); -15.5, -24.7 (s, $\mathrm{H}_{2}$-Im). ${ }^{1} \mathrm{H}$ NMR (trans-isomer, $\mathrm{CDCl}_{3}$ ): 60.0 (s, $\mathrm{CH}_{3}$-ma); 3.7. (s, $\left.H_{5}-\mathrm{Im}\right)$; - 19.6 ( $\mathrm{s}, \mathrm{H}_{2}-\mathrm{Im}$ ). IR (KBr pellet): v $3145(\mathrm{~N}-\mathrm{H}, \mathrm{m}), 1603(\mathrm{C}=\mathrm{O}, \mathrm{s}), 1467$ (s), 1263 (s). LR-MS (+LSIMS, thioglycerol): $488\left(\mathrm{M}^{+}\right), 420\left(\mathrm{M}^{+}-\mathrm{Im}\right), 352\left(\mathrm{M}^{+}-2 \mathrm{Im}\right)$. $\mathrm{CV}(\mathrm{MeCN}): \mathrm{E}_{1 / 2}\left(\mathrm{Ru}^{\mathrm{IIIIII}}\right)=-0.705 \mathrm{~V} . \Lambda_{\mathrm{M}}(\mathrm{MeOH})=119 \Omega^{-1} \mathrm{~cm}^{2} \mathrm{~mol}^{-1}$. Anal. Calcd for $\mathrm{C}_{19} \mathrm{H}_{18} \mathrm{~F}_{3} \mathrm{~N}_{4} \mathrm{O}_{9} \mathrm{SRu}: \mathrm{C}, 35.85 ; \mathrm{H}, 2.83$; N, 8.81. Found: C, 35.92; H, 2.92; N, 8.73.

### 3.7.7 $\left[\mathrm{Ru}(\mathrm{ma})_{2}(\mathbf{1 M e I m})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3} \cdot \mathrm{CH}_{2} \mathrm{Cl}_{2}$ (8)

To a red solution of $1(0.080 \mathrm{~g}, 0.17 \mathrm{mmol})$ in $\mathrm{EtOH}(5 \mathrm{~mL})$, triflic acid was added $(0.028 \mathrm{~g}, 0.19 \mathrm{mmol})$ under $\mathrm{N}_{2}$ and the solution stirred at r.t. for 1 h . After 1 h ,

1 MeIm was added $(0.062 \mathrm{~g}, 0.76 \mathrm{mmol})$ and the solution was stirred for an additional 24 h. After 6 h the solution was checked by $\mathrm{TLC}\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}: \mathrm{MeOH}, 10: 1\right): 6$ bands were observed with the most intense being a red one at $R_{f}=0.6$. After 18 h a similar analysis revealed two major bands, a red one at $R_{f}=0.6$ and a less intense blue one at $R_{f}=0.35$. After 24 h the solvent was removed under vacuum and the dark red residue was dissolved in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(\sim 2 \mathrm{~mL})$ and mounted on a $20 \times 20 \mathrm{~cm}$ silica preparative TLC plate that was developed with $\mathrm{CH}_{2} \mathrm{Cl}_{2}: \mathrm{MeOH}, 12: 1(130 \mathrm{~mL})$. The red band was cut out, added to 50 mL of $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ with 1 mL MeOH , and the mixture was left stirring for 16 h . Attempts to extract the blue band were unsuccessful. The red suspension was then filtered to remove the silica and the volume was reduced to $\sim 3 \mathrm{~mL}$. Hexanes $(20 \mathrm{~mL})$ were then added and the resulting red precipitate was collected, washed with hexanes $(2 \times 5 \mathrm{~mL})$ and dried at $78{ }^{\circ} \mathrm{C}$ under vacuum for 48 h . Yield: $0.060 \mathrm{~g}(48 \%) .{ }^{1} \mathrm{H} \operatorname{NMR}\left(\mathrm{CDCl}_{3}\right): \delta 62.0(\mathrm{br} \mathrm{s}$, $\mathrm{CH}_{3}$-ma); 13.4 (br s, $\mathrm{CH}_{3}$-1MeIm); -3.8 br (s, $H_{5}$-1MeIm); -19.0 (br s, $\mathrm{H}_{2}$-1MeIm). IR (KBr pellet): v 3458 (m), 1601 ( $\mathrm{C}=\mathrm{O}, \mathrm{s}$ ), 1467 ( s ), 1263 ( s ), 1031 (s). LR-MS (+LSIMS, thioglycerol): $516\left(\mathrm{M}^{+}\right), 434\left(\mathrm{M}^{+}-1 \mathrm{MeIm}\right), 352\left(\mathrm{M}^{+}-2(1 \mathrm{MeIm})\right.$ ). CV (MeCN): $\mathrm{E}_{1 / 2}$ $\left(\mathrm{Ru}^{\text {IIIIII }}\right)=-0.765 \mathrm{~V} . \Lambda_{\mathrm{M}}(\mathrm{MeOH})=109 \Omega^{-1} \mathrm{~cm}^{2} \mathrm{~mol}^{-1}$. Anal. Calcd for $\mathrm{C}_{21} \mathrm{H}_{22} \mathrm{~F}_{3} \mathrm{~N}_{4} \mathrm{O}_{9} \mathrm{SRu} \cdot \mathrm{CH}_{2} \mathrm{Cl}_{2}$ : C, 35.25; H, 3.20; N, 7.48. Found: C, 35.71; H, 3.22; N, 7.86.

### 3.7.8 $\quad\left[\mathrm{Ru}(\mathrm{ma})(\mathbf{1 M e I m})_{4}\right]\left[\mathrm{CF}_{3} \mathrm{SO}_{3}\right]_{2}$ (9)

To a red solution of $1(0.067 \mathrm{~g}, 0.14 \mathrm{mmol})$ in $\mathrm{EtOH}(5 \mathrm{~mL})$, triflic acid was added ( $0.054 \mathrm{~g}, 0.36 \mathrm{mmol}$ ) under $\mathrm{N}_{2}$ and the solution stirred at r.t. for 1 h . After 1 h , 1 MeIm was added $(0.077 \mathrm{~g}, 1.1 \mathrm{mmol})$ and the solution was refluxed 48 h . After 24 h the solution was checked by TLC $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}: \mathrm{MeOH}, 10: 1\right): 2$ major bands were observed of approximately equal intensity; a red band at $R_{f}=0.6$, and a blue band at $R_{f}=0.35$. After 48 h , analysis revealed a major blue band $\left(\mathrm{R}_{\mathrm{f}}=0.35\right)$, several minor bands $\left(\mathrm{R}_{\mathrm{f}}=0.2\right.$ $0.7)$, and a black spot $\left(R_{f}=0\right)$. The solvent was removed under vacuum and the dark blue residue was dissolved in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(\sim 1.5 \mathrm{~mL})$ and mounted on a $20 \times 20 \mathrm{~cm}$ silica preparative TLC plate that was developed with $\mathrm{CH}_{2} \mathrm{Cl}_{2}: \mathrm{MeOH}, 10: 1(130 \mathrm{~mL})$. The blue band was cut out, added to 50 mL of $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ with 2 mL MeOH , and the mixture was left stirring for 16 h . The blue mixture was then filtered to remove the silica and the volume was reduced to $\sim 1 \mathrm{~mL}$. Hexanes $(10 \mathrm{~mL})$ were then added and the resulting blue
precipitate was collected, washed with hexanes ( $2 \times 5 \mathrm{~mL}$ ) and dried at $78{ }^{\circ} \mathrm{C}$ under vacuum for 48 h . Yield: $0.055 \mathrm{~g}(46 \%) .{ }^{1} \mathrm{H} \operatorname{NMR}\left(\mathrm{CDCl}_{3}\right): \delta 81.6$ (br s, $\mathrm{CH}_{3}$-ma); 25.6, 20.4 (s, $\mathrm{CH}_{3}$-1MeIm); -0.5, -5.7 (s, $H_{5}$-1MeIm); -18.4, -24.0 (s, $H_{2}$-1MeIm). IR ( KBr pellet): $\operatorname{v} 3137$ (m), 1601 ( $\mathrm{C}=\mathrm{O}, \mathrm{s}$ ), 1546 (m), 1470 (m), 1265 ( s$), 1031$ ( s$)$. LR-MS (+LSIMS, thioglycerol): $704\left(\mathrm{M}^{+}+\mathrm{CF}_{3} \mathrm{SO}_{3}\right), 622\left(\mathrm{M}^{\dagger}+\mathrm{CF}_{3} \mathrm{SO}_{3}-1 \mathrm{MeIm}\right), 540\left(\mathrm{M}^{+}+\right.$ $\mathrm{CF}_{3} \mathrm{SO}_{3}-21 \mathrm{MeIm}$ ), $458\left(\mathrm{M}^{+}+\mathrm{CF}_{3} \mathrm{SO}_{3}-31 \mathrm{MeIm}\right.$ ), $391\left(\mathrm{M}^{+}-21 \mathrm{MeIm}\right), 309\left(\mathrm{M}^{+}-3\right.$ lMeIm). $\mathrm{CV}(\mathrm{MeCN}): \mathrm{E}_{1 / 2}\left(\mathrm{Ru}^{\text {II/II }}\right)=-0.442 \mathrm{~V} . \Lambda_{\mathrm{M}}(\mathrm{MeOH})=273 \Omega^{-1} \mathrm{~cm}^{2} \mathrm{~mol}^{-1}$. Anal. Calcd for $\mathrm{C}_{24} \mathrm{H}_{29} \mathrm{~F}_{6} \mathrm{~N}_{8} \mathrm{O}_{9} \mathrm{~S}_{2} \mathrm{Ru}$ : C, 33.80; H, 3.40; N, 13.14. Found: C, 33.23; H, 3.34; N, 12.73.

### 3.7.9 $\left[\mathrm{Ru}(\mathrm{ma})_{2}(\mathbf{2 M e I m})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$ (10)

To a red solution of $1(0.092 \mathrm{~g}, 0.193 \mathrm{mmol})$ in $\mathrm{EtOH}(5 \mathrm{~mL})$, triflic acid was added $(0.0320 \mathrm{~g}, 0.213 \mathrm{mmol})$ under $\mathrm{N}_{2}$ and the solution stirred at r.t. for 1 h . After 1 h , 2MeIm was added ( $0.066 \mathrm{~g}, 0.805 \mathrm{mmol}$ ) and the solution was stirred for an additional 12 h. The solvent was then removed under vacuum and the dark red residue was dissolved in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(\sim 2 \mathrm{~mL})$ and mounted on a $20 \times 20 \mathrm{~cm}$ silica preparative TLC plate that was developed with $\mathrm{CH}_{2} \mathrm{Cl}_{2}: \mathrm{MeOH}, 20: 1(130 \mathrm{~mL})$. The resulting single, red band was cut out, added to $\mathrm{CH}_{2} \mathrm{Cl}_{2}(50 \mathrm{~mL})$, and the mixture was left stirring for 16 h . The red mixture was then filtered to remove the silica and the volume was reduced to $\sim 2 \mathrm{~mL}$. Hexanes $(10 \mathrm{~mL})$ were then added and the resulting red product was collected, washed with hexanes ( $2 \times 5 \mathrm{~mL}$ ) and dried at $78{ }^{\circ} \mathrm{C}$ under vacuum for 48 h . Yield: $0.063 \mathrm{~g}(56 \%) .{ }^{1} \mathrm{H}$ NMR ( $\mathrm{CDCl}_{3}$ ): $\delta 67.0$ (br s, $\mathrm{CH}_{3}$-ma); 42.0 (br s $\mathrm{CH}_{3}$-Im); -1.6 (br s, $H_{5}$-Im); -4.7 (br s, $H_{4}-\mathrm{Im}$ ). IR (KBr pellet): v 3216 ( $\mathrm{N}-\mathrm{H}, \mathrm{m}$ ), 1602 ( $\mathrm{C}=\mathrm{O}, \mathrm{s}$ ), 1447 ( s ), 1265 ( s ). LR-MS (+LSIMS, thioglycerol): $516\left(\mathrm{M}^{+}\right), 434\left(\mathrm{M}^{+}-2 \mathrm{MeIm}\right), 352\left(\mathrm{M}^{+}-2\right.$ (2MeIm)). CV $(\mathrm{MeCN}): \mathrm{E}_{1 / 2}\left(\mathrm{Ru}^{\text {IILII }}\right)=-0.844 \mathrm{~V} . \Lambda_{\mathrm{M}}(\mathrm{MeOH})=121 \Omega^{-1} \mathrm{~cm}^{2} \mathrm{~mol}^{-1}$. Anal. Calcd for $\mathrm{C}_{21} \mathrm{H}_{22} \mathrm{~F}_{3} \mathrm{~N}_{4} \mathrm{O}_{9}$ SRu: C, 37.95 ; H, 3.31; N, 8.43. Found: C, 37.61 ; H, 3.38; N, 8.20.

### 3.7.10 $\left[\mathrm{Ru}(\text { Ema })_{2}(\text { metro })_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$ (11)

This complex was prepared using the same procedure as described for complex $\mathbf{3}$, but using 2 instead of $1(0.065 \mathrm{~g}, 0.125 \mathrm{mmol})$, triflic acid ( $0.0213 \mathrm{~g}, 0.141 \mathrm{mmol})$ and metro $(0.094 \mathrm{~g}, 549 \mathrm{mmol})$. The green species for this reaction could not be isolated as
was the case with 4. Yield: $0.0642 \mathrm{~g}(59 \%) .{ }^{1} \mathrm{H}$ NMR (acetone- $d_{6}$ ): $\delta 65.3$ (br s, $\mathrm{CH}_{3} \mathrm{CH}_{2}$-Ema); 32.2 (br s, $\mathrm{CH}_{3}$-metro); -4.8 (br s, $H_{5}$-metro). IR ( KBrpellet ): v 3439 ( $\mathrm{O}-$ $\mathrm{H}, \mathrm{m}), 1600$ (C=O, s), 1560 ( $\mathrm{N}-\mathrm{O}_{\text {asym }}, \mathrm{m}$ ), 1367 ( $\mathrm{N}-\mathrm{O}_{\text {sym }}, \mathrm{m}$ ), 1265 (s). LR-MS (+LSIMS, thioglycerol): $722\left(\mathrm{M}^{+}\right), 551\left(\mathrm{M}^{+}\right.$- metro), $380\left(\mathrm{M}^{+}-2\right.$ metro). CV (MeCN): $\mathrm{E}_{1 / 2}\left(\mathrm{NO}_{2} / \mathrm{NO}_{2}^{-}\right)=-1.137 \mathrm{~V}, \mathrm{E}_{1 / 2}\left(\mathrm{Ru}^{\text {iIIIII }}\right)=-0.568 \mathrm{~V}, \mathrm{E}_{1 / 2}\left(\mathrm{Ru}^{\text {IV/III }}\right)=0.967 \mathrm{~V}$ vs. SCE . Anal. Calcd for $\mathrm{C}_{27} \mathrm{H}_{32} \mathrm{~F}_{3} \mathrm{~N}_{6} \mathrm{O}_{15}$ SRu: C, 36.49; H, 3.86; $\mathrm{N}, 9.46$. Found: $\mathrm{C}, 36.52 ; \mathrm{H}, 3.72$; N, 9.55.

### 3.7.11 $\left[\mathrm{Ru}(\mathrm{Ema})_{2}(\mathbf{4 M e I m})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}{ }_{\mathbf{( 1 2})}$

To a red solution of $2(0.060 \mathrm{~g}, 0.116 \mathrm{mmol})$ in EtOH ( 5 mL ) was added triflic acid $\left(0.0220 \mathrm{~g}, 0.146 \mathrm{mmol}\right.$ ) under $\mathrm{N}_{2}$ and the solution stirred at r.t. for 1 h . After 1 h , 4 MeIm was added $(0.038 \mathrm{~g}, 0.463 \mathrm{mmol})$ and the solution was stirred for an additional 16 h. After 3 h the solution was checked by $\mathrm{TLC}\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}: \mathrm{MeOH}, 10: 1\right)$. A single major red band ( $\mathrm{R}_{\mathrm{f}}=0.60$ ) was present with a minor brown one ( $\mathrm{R}_{\mathrm{f}}=0$ ). After 16 h the solvent was removed under vacuum and the reddish-brown residue was dissolved in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ and mounted on a $20 \times 20 \mathrm{~cm}$ silica preparative TLC plate that was developed with $\mathrm{CH}_{2} \mathrm{Cl}_{2}: \mathrm{MeOH}, 20: 1$ ( 130 mL ). The major band was cut out, added to 50 mL of $\mathrm{CH}_{2} \mathrm{Cl}_{2}: \mathrm{MeOH}$ (49:1), and the mixture was stirred for 16 h . The red mixture was then filtered to remove the silica and the volume was reduced to $\sim 1 \mathrm{~mL}$. Hexanes ( 15 mL ) were then added and the resulting dark red precipitate was collected, washed with hexanes ( $3 \times 5 \mathrm{~mL}$ ) and dried at $78{ }^{\circ} \mathrm{C}$ under vacuum for 48 h . Yield: $0.0449 \mathrm{~g}(56 \%)$. ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CD}_{2} \mathrm{Cl}_{2}\right): \delta 49.1$ (br s, $\mathrm{CH}_{3} \mathrm{CH}_{2}$-Ema); 16.5 (br s, $\mathrm{CH}_{3}-4 \mathrm{MeIm}$ ); -4.6 (br s, $\mathrm{H}_{5}-$ 4MeIm); -19.0 (br s, $\left.H_{2}-4 \mathrm{MeIm}\right)$. IR (KBr pellet): v 3439 ( $\mathrm{N}-\mathrm{H}, \mathrm{m}$ ), 1597 ( $\mathrm{C}=\mathrm{O}, \mathrm{s}$ ), 1547 (m), $1473(\mathrm{~m}), 1259$ (s), 1030 (s). LR-MS (+LSIMS, thioglycerol): $544\left(\mathrm{M}^{+}\right), 462\left(\mathrm{M}^{+}\right.$$4 \mathrm{MeIm}), 380\left(\mathrm{M}^{+}-2(4 \mathrm{MeIm})\right) . \mathrm{CV}(\mathrm{MeCN}): \mathrm{E}_{1 / 2}\left(\mathrm{Ru}^{111 / \mathrm{II}}\right)=-0.829 \mathrm{~V}$. Anal. Calcd for $\mathrm{C}_{23} \mathrm{H}_{26} \mathrm{~F}_{3} \mathrm{~N}_{4} \mathrm{O}_{9} \mathrm{SRu}: \mathrm{C}, 39.88 ; \mathrm{H}, 3.76 ; \mathrm{N}, 8.09$. Found: C, 39.48; H, 3.88; $\mathrm{N}, 7.93$.

### 3.7.12 $\left[\mathrm{Ru}(\mathrm{Ema})_{2}{ }_{2} \mathbf{2 M e I m}_{2}\right)_{2} \mathrm{CF}_{3} \mathrm{SO}_{3}$ (13)

This complex was prepared using the same procedure as described for complex 12, but using $2(0.082 \mathrm{~g}, 0.158 \mathrm{mmol})$, triflic acid $(0.0270 \mathrm{~g}, 0.179 \mathrm{mmol})$, and 2 MeIm $(0.051 \mathrm{~g}, 0.622 \mathrm{mmol}) . \mathrm{R}_{\mathrm{f}}=0.55$ for the major red band of 13 . Yield: $0.0629 \mathrm{~g}(58 \%)$.
${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CD}_{2} \mathrm{Cl}_{2}\right): \delta 51.7$ (br s, $\mathrm{CH}_{3} \mathrm{CH}_{2}$-Ema); 43.7 (br s, $\mathrm{CH}_{3}$ - 2 MeIm ); -1.9 (br s, $\mathrm{H}_{5^{-}}$ 2MeIm); -5.2 (br s, $\left.H_{4}-2 \mathrm{MeIm}\right)$. IR (KBr pellet): v 3463 ( $\mathrm{N}-\mathrm{H}, \mathrm{m}$ ), 1597 (C=O, s), 1548 (m), 1472 (m), 1260 (s), 1031 (s). LR-MS (+LSIMS, thioglycerol): $544\left(\mathrm{M}^{+}\right), 462\left(\mathrm{M}^{+}\right.$$2 \mathrm{MeIm}), 380\left(\mathrm{M}^{+}-2(2 \mathrm{MeIm})\right)$. $\mathrm{CV}(\mathrm{MeCN}): \mathrm{E}_{1 / 2}\left(\mathrm{Ru}^{\text {III/II }}\right)=-0.889 \mathrm{~V}$. Anal. Calcd for $\mathrm{RuC}_{23} \mathrm{H}_{26} \mathrm{~F}_{3} \mathrm{~N}_{4} \mathrm{O}_{9} \mathrm{~S}: \mathrm{C}, 39.88 ; \mathrm{H}, 3.76$; $\mathrm{N}, 8.09$. Found: C, $39.71 ; \mathrm{H}, 3.87$; $\mathrm{N}, 7.82$.

### 3.7.13 $\left[\mathrm{Ru}(\mathrm{ma})_{2}(\mathrm{EF} 5)_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3} \cdot \mathrm{EtOH}$ (14)

To a solution of $3(0.104 \mathrm{~g}, 0.175 \mathrm{mmol})$ in 5 mL EtOH under $\mathrm{N}_{2}$ was added EF5 $(0.106 \mathrm{~g}, 0.351 \mathrm{mmol})$. This solution, on refluxing for 48 h , slowly became brown and finally blue. TLC showed that almost all of the EF5 had been consumed in the reaction and that there was one major blue band, $\mathrm{R}_{\mathrm{f}}=0\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}: \mathrm{MeOH}, 10: 1\right)$. A weak intensity pink band $\mathrm{R}_{\mathrm{f}}=0.6$ was also observed. The solvent was reduced in volume to $\sim 1 \mathrm{~mL}$ and $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ was added ( 10 mL ) to yield a blue precipitate that was collected, and dried at 78 ${ }^{\circ} \mathrm{C}$ under vacuum for 24 h . Yield: $0.098 \mathrm{~g}(51 \%) .{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CD}_{3} \mathrm{OD}\right): \delta 59.2$ (br s, $\mathrm{CH}_{3}$ ma); -4.8 (br s, $H_{5}$-EF5); -16.1 (br s, $H_{4}$-EF5). ${ }^{19} \mathrm{~F}$ NMR ( $\mathrm{CD}_{3} \mathrm{OD}$ ): $\delta-3.52\left(\mathrm{~s}, \mathrm{CF}_{3} \mathrm{SO}_{3}\right.$ ); -8.9 (br s, $\mathrm{CF}_{2} \mathrm{CF}_{3}$ ); -46.1 (br s, $\mathrm{CF}_{2} \mathrm{CF}_{3}$ ). IR ( KBr pellet): $v 3423$ ( $\mathrm{N}-\mathrm{H}, \mathrm{s}$ ), 2924 (C-H, $\mathrm{m}), 1686$ ( $\mathrm{C}=\mathrm{O}, \mathrm{s}$ ), 1602 ( $\mathrm{C}=\mathrm{O}$ ), 1548 (m), 1473 (m), 1264 ( s$), 1202$ (s). LR-MS (+LSIMS, thioglycerol): $940\left(\mathrm{M}^{+}-16\right), 642\left(\mathrm{M}^{+}-\mathrm{EF5}-16\right), 352\left(\mathrm{M}^{+}-2\right.$ EF5). Anal. Calcd for $\mathrm{C}_{29} \mathrm{H}_{26} \mathrm{~F}_{3} \mathrm{~N}_{4} \mathrm{O}_{9} \mathrm{SRu} \cdot \mathrm{C}_{2} \mathrm{H}_{6} \mathrm{O}: \mathrm{C}, 32.34 ; \mathrm{H}, 2.61$; $\mathrm{N}, 9.74$. Found: $\mathrm{C}, 32.17$; H , 2.52; N, 9.97.

### 3.7.14 $\left[\mathrm{Ru}(\mathrm{ma})_{2}\left(2 \mathrm{NO}_{2} \mathrm{Im}\right)_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$ (15)

A solution of $1(0.042 \mathrm{~g}, 0.088 \mathrm{mmol})$ in 5 mL EtOH and triflic acid $(0.014 \mathrm{~g}$, 0.093 mmol ) was refluxed for 1 h under $\mathrm{N}_{2} ; 2 \mathrm{NO}_{2} \operatorname{Im}(0.040 \mathrm{~g}, 0.354 \mathrm{mmol})$ was then added and this solution was refluxed for 24 h . A blue precipitate that formed was then removed by filtration, washed with $\mathrm{MeOH}(2 \times 5 \mathrm{~mL})$ and dried under vacuum at $78{ }^{\circ} \mathrm{C}$ for 48 h . Yield: 0.017 g ( $27 \%$ ). IR ( KBr pellet): v $3431(\mathrm{~N}-\mathrm{H}, \mathrm{s}), 2967(\mathrm{C}-\mathrm{H}, \mathrm{m}), 1653$ (C=O, m), 1542 (m), 1491 ( $\mathrm{N}-\mathrm{O}_{\text {asym }}$, s), 1367 ( $\left.\mathrm{N}-\mathrm{O}_{\text {sym }}, ~ s\right) . \quad$ Anal. Calcd for $\mathrm{C}_{19} \mathrm{H}_{16} \mathrm{~F}_{3} \mathrm{~N}_{6} \mathrm{O}_{13} \mathrm{SRu}: \mathrm{C}, 31.41 ; \mathrm{H}, 2.20$; N, 11.57. Found: C, 32.87 ; H, 2.32; N, 12.97.

### 3.7.15 $\left[\mathrm{Ru}(\mathrm{ma})_{2}\left(4 \mathrm{NO}_{2} \mathrm{Im}\right)_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$ <br> (16)

This complex was prepared using the same procedure as used for complex 15, except using $4 \mathrm{NO}_{2} \mathrm{Im}(0.041 \mathrm{~g}, 0.363 \mathrm{mmol})$ in place of $2 \mathrm{NO}_{2} \mathrm{Im}$ with complex $1(0.043$ $\mathrm{g}, 0.090 \mathrm{mmol}$ ). Yield: $0.016 \mathrm{~g}(24 \%) .{ }^{1} \mathrm{H}$ NMR (acetone- $d_{6}$ ): $\delta 63.8$ (br s, $\mathrm{CH}_{3}-\mathrm{ma}$ ). IR ( KBr pellet): v $3471(\mathrm{~N}-\mathrm{H}, \mathrm{s}), 2883,2821(\mathrm{C}-\mathrm{H}, \mathrm{m}), 1556(\mathrm{C}=\mathrm{O}, \mathrm{m}), 1509(\mathrm{~m}), 1496$ $\left(\mathrm{N}-\mathrm{O}_{\text {asym }}, \mathrm{s}\right), 1380\left(\mathrm{~N}-\mathrm{O}_{\text {sym }}, \mathrm{s}\right)$. Anal. Calcd for $\mathrm{C}_{19} \mathrm{H}_{16} \mathrm{~F}_{3} \mathrm{~N}_{6} \mathrm{O}_{13} \mathrm{SRu}: \mathrm{C}, 31.41 ; \mathrm{H}, 2.20 ; \mathrm{N}$, 11.57. Found: C, 33.02; H, 2.37; N, 12.64 .

### 3.7.16 $\left[\mathrm{Ru}(\mathrm{ma})_{2}\left(\mathbf{3 N O}_{2} \mathrm{tri}\right)_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$

(17)

This complex was prepared using the same procedure as used for complex 15, except using $3 \mathrm{NO}_{2}$ tri $(0.044 \mathrm{~g}, 0.386 \mathrm{mmol})$ in place of $2 \mathrm{NO}_{2} \mathrm{Im}$ with complex $1(0.041$ $\mathrm{g}, 0.086 \mathrm{mmol})$. Yield: $0.022 \mathrm{~g}(35 \%)$. IR (KBr pellet): v 3471 ( $\mathrm{N}-\mathrm{H}, \mathrm{m}$ ), 2883, 2821 (C-H, m), 1556 (C=O, m), 1509 (m), 1496 ( $\mathrm{N}-\mathrm{O}_{\text {asym }}, \mathrm{s}$ ), $1380\left(\mathrm{~N}-\mathrm{O}_{\text {sym }}, \mathrm{s}\right)$. Anal. Calcd for $\mathrm{C}_{19} \mathrm{H}_{16} \mathrm{~F}_{3} \mathrm{~N}_{6} \mathrm{O}_{13} \mathrm{SRu}$ : C, 28.02; H, 1.92; N, 15.38. Found: C, $30.06 ; \mathrm{H}, 2.40 ; \mathrm{N}, 16.47$.

### 3.7.17 $\left[\mathrm{Ru}(\mathrm{ma})_{2}(\mathrm{triF5})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$ (18)

This complex was prepared using the same procedure as used for complex 15, except using triF5 $(0.068 \mathrm{~g}, 0.224 \mathrm{mmol})$ in place of $2 \mathrm{NO}_{2} \mathrm{Im}$ with complex $1(0.041 \mathrm{~g}$, $0.086 \mathrm{mmol})$. Yield: $0.032 \mathrm{~g}(34 \%)$. $\mathrm{IR}(\mathrm{KBr}$ pellet): $v 3435(\mathrm{~N}-\mathrm{H}, \mathrm{m}), 2926(\mathrm{C}-\mathrm{H}, \mathrm{m})$, $1601(\mathrm{C}=\mathrm{O}, \mathrm{m}), 1542(\mathrm{~m}), 1466\left(\mathrm{~N}-\mathrm{O}_{\text {asym }}, \mathrm{m}\right), 1371\left(\mathrm{~N}-\mathrm{O}_{\text {sym }}, \mathrm{w}\right), 1264$ (m). Anal. Calcd for $\mathrm{C}_{27} \mathrm{H}_{22} \mathrm{~F}_{13} \mathrm{~N}_{10} \mathrm{O}_{15} \mathrm{SRu}: \mathrm{C}, 29.29$; $\mathrm{H}, 1.99$; $\mathrm{N}, 12.66$. Found: $\mathrm{C}, 29.43 ; \mathrm{H}, 2.11$; N , 12.24.

### 3.7.18 $\left[\mathrm{Ru}(\mathbf{H M e p y r})_{3}\right] \mathrm{Cl}_{3}$ (19)

To a solution of $\mathrm{RuCl}_{3} \cdot 3 \mathrm{H}_{2} \mathrm{O}(0.103 \mathrm{~g}, 0.394 \mathrm{mmol})$ in $10 \mathrm{~mL} \mathrm{H} \mathrm{H}_{2} \mathrm{O}$ was added HMepyr ( $0.164 \mathrm{~g}, 1.18 \mathrm{mmol}$ ). This solution was stirred for 15 min until it had turned dark purple in colour. The volume was reduced to $\sim 2 \mathrm{~mL}$ and acetone ( 100 mL ) was added. The resulting purple precipitate was collected, and dried under vacuum at $78{ }^{\circ} \mathrm{C}$ for 24 h . Yield: $0.227 \mathrm{~g}(92 \%)$. IR (KBr pellet): v $3419(\mathrm{~N}-\mathrm{H}, \mathrm{s}), 1598(\mathrm{C}=\mathrm{O}, \mathrm{m}), 1497$ (s), 1272 (s). $\Lambda_{M}\left(\mathrm{H}_{2} \mathrm{O}\right)=451 \Omega^{-1} \mathrm{~cm}^{2} \mathrm{~mol}^{-1}$. Anal. Calcd for $\mathrm{C}_{21} \mathrm{H}_{27} \mathrm{~N}_{3} \mathrm{O}_{6} \mathrm{Cl}_{3} \mathrm{Ru}$ : C, 40.35; H, 4.32; N, 6.73. Found: C, 40.52; H, 4.47; N, 6.58.

## Chapter 4

## Synthesis and Characterization of Ru Complexes with 4,4'-Biimidazoles

### 4.1 Introduction

Although the coordination chemistry of 2,2'-biimidazole (Figure 4.1) with Ru and other transition metals has been extensively explored, ${ }^{1-4}$ no complexes have been reported in the literature containing the analogous 4,4 '-biimidazole ligand (biim). Since biim was first synthesized in $1994,{ }^{5}$ its only reported interaction with a transition metal ion was with $\mathrm{Cu}(\Pi)$, to form in situ catalytic systems for making polymers from 2,6dimethylphenol. ${ }^{6}$ No complexes, however, were isolated or characterized in situ.

Figure 4.1 Molecular structure of 2,2'-biimidazole.

It has been suggested that some Ru complexes that show anticancer activity may act through a mechanism similar to that of cisplatin, in which dissociation of N -donor ligands such as imidazoles (instead of $\mathrm{Cl}^{-}$as is the case for cisplatin), inside the cell, renders coordination sites available for DNA bases to bind the metal. ${ }^{7}$ In such cases, however, any information contained in the imidazole ligand (e.g. radiolabels, fluorescent tags), is lost upon ligand dissociation. Bidentate imidazole ligands, with their ability to bind the metal centre more strongly through the chelate effect, could in principle remain bound in situ to a higher degree than their monodentate analogues and functional groups within the imidazole would then remain associated with the complex and could be targeted to the DNA. In this chapter, the synthesis and characterization of Ru complexes containing chelating 4,4'-biimidazole ligands will be discussed.

### 4.2 Synthesis and Reactions of 4,4'-Biimidazoles

### 4.2.1 Synthesis of 4,4'-Biimidazoles

These compounds were synthesized using modified procedures of those published by Cliff and Pyne. ${ }^{5}$ The syntheses of both 4,4 '-biimidazolium trifluoroacetate $\left(\mathrm{H}_{2}\right.$ biim $)$ and 2,2'-dimethyl-4,4'-biimidazolium trifluoroacetate $\left(\mathrm{H}_{2} \mathrm{Me}_{2}\right.$ biim) require 5 steps each, when conducted from the starting materials Im and 2MeIm, respectively (Figure 4.2). While the synthesis of $\mathrm{H}_{2}$ biim is straightforward, that of $\mathrm{H}_{2} \mathrm{Me}_{2}$ biim required several modifications to the published procedure. Some of the refinements made for the

$R=H, M e$

$\mathrm{R}=\mathrm{I}, \mathrm{Me}$

$\mathrm{R}=\mathrm{H}, \mathrm{Me}$

$\mathrm{R}=\mathrm{H}, \mathrm{Me}$

Figure 4.2 Synthesis for $\mathrm{H}_{2}$ biim and $\mathrm{H}_{2} \mathrm{Me}_{2}$ biim.
synthesis of $\mathrm{H}_{2} \mathrm{Me}_{2}$ biim were then applied to give a higher yield synthesis of $\mathrm{H}_{2} \mathrm{biim}$. In the first step of the $\mathrm{H}_{2} \mathrm{Me}_{2}$ biim synthesis, formation of 4,5-diiodo-2-methylimidazole (Section 4.8.7), the reported rapid addition of $\mathrm{I}_{2}$ to the biphasic $\mathrm{CHCl}_{3} / \mathrm{aq} . \mathrm{NaOH}$ system led to the formation of a brown emulsion that did not separate into two phases again over 24 h . To overcome this problem, the total amount of $\mathrm{I}_{2}$ must be slowly added in 5 g increments over 20 min , allowing it to dissolve entirely after each addition. In the synthesis of $\mathrm{H}_{2}$ biim this modification was not required. A modified procedure was also adopted in the second step (Section 4.8.8), precipitation of the monoiodo-imidazole species, whereby addition of EtOH to the $\mathrm{EtOH} /$ water solution precipitated many of the Na salts which were then removed by filtration. The filtrate was then boiled to remove the EtOH and reduced in volume until the product, 4-iodo-2-methylimidazole, began to precipitate. This modification was also applied to give a higher yield synthesis of 4(5)iodoimidazole (Section 4.8.3). As well, protection of the NH proton of 4-iodo-2methylimidazole (third step), according to the literature that reported a $1: 1$, chlorotriphenylmethane:imidazole ratio, resulted in the isolation of a product containing a large excess of the trityl group (determined by ${ }^{1} \mathrm{H}$ NMR spectroscopy), presumably present as triphenylmethanol, which can form in $\mathrm{H}_{2} \mathrm{O}$ under basic conditions. ${ }^{8}$ Chromatographic separation of the product from this impurity could not be achieved because of their almost identical $\mathrm{R}_{\mathrm{f}}$ values. By increasing the ratio of imidazole:trityl chloride to $1.5: 1$, it was found that 4-iodo-2-methyl-1-(triphenylmethyl)imidazole was isolable in pure form. The crude product containing the triphenylmethanol impurity does not undergo the next reaction step (Suzuki coupling); instead a black precipitate is formed which displays a single resonance for $\mathrm{PPh}_{3}$ in the ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum in $\mathrm{CDCl}_{3}$ and no evidence for either the methyl or $\mathrm{H}(5)$ imidazole signals in the ${ }^{1} \mathrm{H}$ NMR spectrum.

It is important that the protected iodoimidazole species be pure before performing the coupling reaction. Purity was assessed by checking the relative integration values for the aromatic protons, Me protons, and $\mathrm{H}(5)$ proton of the imidazole species. As the residual $\mathrm{CHCl}_{3}$ resonance in $\mathrm{CDCl}_{3}$ overlaps with those of the aromatic signals, the ${ }^{1} \mathrm{H}$ NMR spectra were recorded in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$ in order to avoid inaccurate integrations. The 15:3
aromatic region:methyl integration ratio for 4-iodo-2-methyl-1-(triphenylmethyl)imidazole is consistent with the formulation. ${ }^{5}$ A singlet at $\delta 6.72\left(6.75\right.$ in $\mathrm{CDCl}_{3}$, Section 4.8.9) integrating for one proton is observed for the imidazole $\mathrm{H}(5)$ proton. For 4-iodo-1(triphenylmethyl)imidazole (Section 4.8.4), as the aromatic region overlaps the $\mathrm{H}(2)$ resonance of the imidazole, the aromatic region: $\mathrm{H}(5)$-imidazole integration ratio is $16: 1$. The singlet for the $\mathrm{H}(5)$ proton at $\delta 6.87$ ( 6.92 in $\mathrm{CDCl}_{3}$, Section 4.8.4) is shifted out of the aromatic region.

The Suzuki coupling for preparing both 4,4'-biimidazoles was performed according to the published procedure; ${ }^{5}$ however, considerably improved yield and purity in the desired product can be obtained ( 78 vs . $43 \%$ for $1,1^{\prime}$-bis(triphenylmethyl)-4,4'biimidazole and 69 vs. $27 \%$ for 2,2'-dimethyl-1,1'-bis(triphenylmethyl)-4,4'-biimidazole) when the catalyst, $\mathrm{Pd}\left(\mathrm{PPh}_{3}\right)_{4}$, is freshly prepared ${ }^{9}$ just prior to use. The protecting groups were removed in step 5 to afford $\mathrm{H}_{2}$ biim (Section 4.8.6) and $\mathrm{H}_{2} \mathrm{Me}_{2}$ biim (Section 4.8.11) according to the reported procedures. ${ }^{5}$

X-ray quality crystals of 1,1 '-bis(triphenylmethyl)-4,4'-biimidazole were grown from slow evaporation of a $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ solution of the compound (Figure 4.3). The imidazole rings are essentially co-planar (the torsion angle between them is 0.8 degrees), and the molecule has a centre of inversion. The $\mathrm{C} 4-\mathrm{C} 4$ bond length is $1.448 \AA$, intermediate between that observed for the $\mathrm{C} 4=\mathrm{C} 5$ double bond ( $1.353 \AA$ ) and the single bond between C-Ph ( $1.544 \AA$ ) in the protecting group.

Figure 4.3 ORTEP diagram of 1,1 '-bis(triphenylmethyl)-4,4'-biimidazole with $50 \%$ probability thermal ellipsoids (see Appendix A5 for details).

### 4.2.2 Attempted Nitration of $\mathbf{H}_{2}$ biim

2-Nitroimidazoles are known to accumulate in hypoxic cells, and by nitrating $\mathrm{H}_{2}$ biim, one could potentially synthesize new hypoxic markers. ${ }^{10}$ Such bidentate nitrobiimidazole ligands might also bind more strongly to metal centres than do nitroimidazoles, thus leading to increased stability of the nitroimidazole-type complexes in situ.

Nitration at the $4,4^{\prime}$ and $5,5^{\prime}$ positions of 2,2'-biimidazole using conc. $\mathrm{HNO}_{3}$ has been reported, and 4,4',5,5'-tetranitro-2, $2^{\prime}$-biimidazole has been characterized by X-ray diffraction. ${ }^{11,12}$ The di-substituted derivative, 4,4'-dinitro-2,2'-biimidazole, has also been synthesized, again using conc. $\mathrm{HNO}_{3}$ as the nitrating agent; however, its characterization solely by elemental analysis leaves some ambiguity as to the actual position of the nitro groups. ${ }^{13}$ In this thesis work, attempts were made to nitrate $\mathrm{H}_{2}$ biim selectively at the $2,2^{\prime}$ positions, to obtain a bidentate analogue of $2 \mathrm{NO}_{2} \mathrm{Im}$. In the case of imidazole itself, nitration with conc. $\mathrm{HNO}_{3}$ takes place preferentially at the $\mathrm{H}(4)$ position, and in the case of 4 MeIm , the $\mathrm{H}(5)$ position is nitrated preferentially over the $\mathrm{H}(2)$ position. ${ }^{14,15}$ In this thesis work, nitration of $1,1^{\prime}$-bis(triphenylmethyl)-4,4'-biimidazole at the $2,2^{\prime}$-positions was attempted following the procedure described by Davis et al. for the nitration of 1(triphenylmethyl)imidazole at the 2-position using $n$-propyl nitrate. ${ }^{16}$ 1,1'-Bis(triphenylmethyl)-4,4'-biimidazole, however, is insoluble in non-chlorinated solvents and no reaction was observed upon treatment of a suspension of this biimidazole in THF, dioxane or hexanes, with $n-B u L i$, even at refluxing temperatures. Attempts to synthesize the desired 2,2'-dinitro-4,4'-biimidazole via an alternate route, namely Suzuki coupling of two $2 \mathrm{NO}_{2} \operatorname{Im}$ derivatives, were also unsuccessful. 4-Bromo-1-methyl-2-nitroimidazole has been reported ${ }^{17,18}$ but the described syntheses proceed in low yield ( $<40 \%$ ). 4-Bromo-2-nitroimidazole has also been reported, but the pure compound could not be isolated from the reaction mixture. ${ }^{17}$ It was also determined (Section 4.3) that the Suzuki coupling step does not tolerate a nitro functional group on the reactant.

### 4.3 Attempted Synthesis of 5,5'-Dinitro-3,3'-bi(1,2,4-triazole)

Work with 3-nitro-1,2,4-triazoles as potential anticancer agents suggests that nitrotriazoles can act in a manner similar to that of nitroimidazoles. ${ }^{19}$ The synthesis of 5,5'-diamino-3,3'-bi(1,2,4-triazole) (bisAT) (Figure 4.4) has been reported in a patent, ${ }^{20}$ and an improved procedure subsequently established by a member of our group led to bisAT being obtained in $76 \%$ yield. ${ }^{21}$ The synthesis of the corresponding 5,5'-dinitro-3,3'-bi(1,2,4-triazole) from bisAT using a described literature procedure ${ }^{22}$ was unsuccessful. The procedure involved reacting the amino groups with conc. $\mathrm{H}_{2} \mathrm{SO}_{4}$ and $\mathrm{NaNO}_{2}$ to form diazonium salts that can then undergo substitution reactions with $\mathrm{NaNO}_{2}$ to form the dinitro species. Even after several extractions of the aqueous reaction mixture with ethyl acetate, no product was observed. Attempts to isolate the bitriazole from the aqueous mixture by neutralizing the solution, removing the solvent, and triturating the residue with ethyl acetate, yielded a solid which showed no evidence of any nitro groups by IR spectroscopy and no evidence for the bitriazole unit by ESI-MS. Conversely, the same procedure was successfully employed in the nitration of 3-amino-1,2,4-triazole-5-carboxylic acid (see Section 5.4) to yield the corresponding 3-nitro compound. Suzuki coupling of 3-iodo-5-nitrotriazole to afford the desired dinitrobitriazole was also unsuccessful; the $\mathrm{Pd}\left(\mathrm{PPh}_{3}\right)_{4}$ catalyst may react with the nitro group itself, thus decomposing both reactant and catalyst.

Figure 4.4 Molecular structure of 5,5'-diamino-3,3'-bi(1,2,4-triazole).

### 4.4 Ru-biim Complexes Synthesized from cis-RuCl $\mathbf{2}_{2}(\mathbf{D M S O})_{4}$

Complexes of the type $\mathrm{RuCl}_{2}(\mathrm{DMSO})_{2} \mathrm{~L}_{2}$ ( $\mathrm{L}=$ imidazole or nitroimidazole) have been synthesized from the precursor cis $-\mathrm{RuCl}_{2}(\mathrm{DMSO})_{4}$ by our group, ${ }^{23}$ although no crystal structures were performed to determine unambiguously the geometries of the complexes. ${ }^{23}$ Similarly, the addition of one equiv. of a biimidazole to the same precursor was expected to lead to the displacement of 2 DMSO ligands with formation of the analogous complex containing one bidentate biimidazole in place of 2 monodentate imidazole ligands, and indeed a $1: 1$ reaction of $\mathrm{H}_{2}$ biim with $\mathrm{RuCl}_{2}(\mathrm{DMSO})_{4}$ gives the monomeric $\mathrm{RuCl}_{2}(\mathrm{DMSO})_{2}$ (biim) species (20).

The ${ }^{1} \mathrm{H}$ NMR spectrum of a solution species formed from $\mathbf{2 0}$ in $\mathrm{CD}_{3} \mathrm{OD}$ displays 4 resonances for the biimidazole protons indicating that each of the two rings inhabits a different chemical environment (Figure 4.5c, this region of the spectrum is identical for isolated and in situ formed 20); four different resonances are also detected for the DMSO methyl groups, indicating that each of them is inequivalent in solution. Only the all cisisomer (Figure 4.6) in the solid state (as precursor of the solution species), perhaps accounts for these observations. Figure 4.5a shows the resonances for the free ligand, $\mathrm{H}_{2}$ biim, in $\mathrm{CD}_{3} \mathrm{OD}$ to show how the spectrum of the ligand changes upon coordination to the metal centre (Figure 4.5 c ). The conductivity of $\mathbf{2 0} \mathrm{in} \mathrm{MeOH}\left(127 \Omega^{-1} \mathrm{~cm}^{2} \mathrm{~mol}^{-1}\right)$, is in the range for a $1: 1$ electrolyte ${ }^{24}$ thus showing that one $\mathrm{Cl}^{-}$ligand is dissociated in solution. An all cis structure has been demonstrated crystallographically for the similar complex $\mathrm{RuCl}_{2}(\mathrm{DMSO})_{2}(1,2 \text {-dimethylimidazole })_{2},{ }^{25}$ this finding contrasts, however, with those from our group for a related compound containing a chelating sulfoxide, trans$\mathrm{RuCl}_{2}[R, R-1,2 \text {-bis(ethylsulfinyl)ethane](metro) })_{2}$, in which the chloride ligands are mutually trans in the solid state structure as determined by X-ray diffraction, although the solution ${ }^{1} \mathrm{H}$ NMR spectrum in $\mathrm{D}_{2} \mathrm{O}$ shows a mixture of cis- and trans-isomers. ${ }^{26}$

The ${ }^{1} \mathrm{H}-{ }^{1} \mathrm{H}$ COSY NMR spectrum of 20 shows correlation between the two DMSO singlets at $\delta 2.29$ and 3.01 and between those at $\delta 3.23$ and 3.49 (Figure 4.7), each pair corresponding to the two Me groups within one DMSO ligand. Similarly, the resonances for the $\mathrm{H}(5)$ and $\mathrm{H}(2)$ imidazole protons on each ring also correlate with each

Figure 4.5 ${ }^{1} \mathrm{H}$ NMR spectra ( $300 \mathrm{MHz}, 298 \mathrm{~K}$ ) in $\mathrm{CD}_{3} \mathrm{OD}$ showing the imidazole protons of a) free $\mathrm{H}_{2}$ biim in $\mathrm{CD}_{3} \mathrm{OD}$, b) $1: 2 \mathrm{H}_{2}$ biim: $\mathrm{RuCl}_{2}(\mathrm{DMSO})_{4}$ after 4 h at $65{ }^{\circ} \mathrm{C}$ in $\mathrm{CD}_{3} \mathrm{OD}$, and c) $1: 1 \mathrm{H}_{2}$ biim: $\mathrm{RuCl}_{2}(\mathrm{DMSO})_{4}$ after 4 h at 65 ${ }^{\circ} \mathrm{C}$ in $\mathrm{CD}_{3} \mathrm{OD}$. The spectra for isolated 21 and 20 in $\mathrm{CD}_{3} \mathrm{OD}$ are identical to those in (b) and (c), respectively, in this region.

Figure 4.6 Proposed solid state structure for $\mathrm{RuCl}_{2}(\mathrm{DMSO})_{2}($ biim $)$.

Figure $4.7{ }^{1} \mathrm{H}-{ }^{1} \mathrm{H}$ COSY NMR spectrum ( $300 \mathrm{MHz}, 298 \mathrm{~K}$ ) of 20 in $\mathrm{CD}_{3} \mathrm{OD}$. a) Complete spectrum. b) Expansion showing correlation of imidazole protons. c) Expansion showing correlation of DMSO protons. Small peaks at $\delta 3.38$ and 2.65 are due to $\mathrm{Ru}_{2} \mathrm{Cl}_{4}(\mathrm{DMSO})_{4}($ biim ) (21) (see text).
other, showing that the signals at $\delta 8.39$ and 7.67 belong to the $\mathrm{H}(2)$ and $\mathrm{H}(5)$ of one ring and those at $\delta 8.37$ and 7.72 to the $\mathrm{H}(2)$ and $\mathrm{H}(5)$ on the other ring, respectively.

From the ${ }^{1} \mathrm{H}$ NMR spectrum, it appears as if there is one S-bound DMSO $(\delta 3.23$ and 3.49) and one O-bound DMSO ( $\delta 2.29$ and 3.01) present; however, the IR shows two strong $\mathrm{S}=\mathrm{O}$ stretches at 1071 and $1067 \mathrm{~cm}^{-1}$, both in the region for S-bound DMSO. No $\operatorname{IR}$ bands are observed for O-bound DMSO (typically $900-1000 \mathrm{~cm}^{-1}$ for $\mathrm{Ru}(\mathrm{II})$ complexes). ${ }^{27 a}$ The possible upfield shift of the resonances at $\delta 3.01$ and 2.29 may arise from an interaction between the Me protons on the S-bound DMSO (cis to biim) and the $\pi$-system of biim.

The mass spectrum of this complex (Figure 4.8) is consistent with the proposed formulation, clearly showing the $\mathrm{M}^{+}$species, as well as fragments corresponding to the loss of one $\mathrm{Cl}^{-}$and to the subsequent loss of one DMSO ligand. Elemental analysis was also consistent with the formulation. By increasing the $\mathrm{H}_{2}$ biim: Ru ratio to $2: 1$, it was expected that two biim ligands might displace all 4 DMSO ligands of the starting material as is the case when $\mathrm{RuCl}_{2}(\mathrm{DMSO})_{4}$ is reacted with pyridine to afford cisRu (pyridine) $)_{4} \mathrm{Cl}_{2} ;{ }^{28}$ however, only $\mathbf{2 0}$ could be isolated from this reaction. Attempts to further substitute $\mathbf{2 0}$ with a 5-fold excess of $\mathrm{H}_{2}$ biim were also unsuccessful.

Figure 4.8 Mass spectrum of $\mathrm{RuCl}_{2}(\mathrm{DMSO})_{2}$ (biim) (20): the most intense group of signals is for $\left(\mathrm{M}^{+}-\mathrm{Cl}-\mathrm{DMSO}\right)$. The parent peak is the small cluster centred at 463.

Reaction of $\mathrm{H}_{2}$ biim with $\mathrm{RuCl}_{2}(\mathrm{DMSO})_{4}\left(\mathrm{H}_{2}\right.$ biim: $\left.\mathrm{Ru}, 1: 2\right)$ results in the formation of a bimetallic complex, $\mathrm{Ru}_{2} \mathrm{Cl}_{4}(\mathrm{DMSO})_{4}$ (biim) (21). Elemental analysis supports this formulation and an $\left[\mathrm{M}^{+}-\mathrm{Cl}\right]$ fragmentation splitting pattern characteristic for this formulation is observed in the mass spectrum (see Figure 5.4 for description of splitting pattern differences between Ru and $\mathrm{Ru}_{2}$ ). The splitting pattern differs from that of $\mathbf{2 0}$ as it clearly shows the isotopic distribution for a unit with two Ru atoms present. The ${ }^{1} \mathrm{H}$ NMR spectrum of a solution form of 21, made in situ in $\mathrm{CD}_{3} \mathrm{OD}$, displays two major resonances for the $\mathrm{H}(2)$ and $\mathrm{H}(5)$ protons of the bound biim (Figure 4.4b). This indicates that each set of protons within the two rings is in an equivalent chemical environment, and is consistent with a solid-state formulation in which the biim ligand is situated trans to two bridging chlorides (Figure 4.9). In the region of the ${ }^{1} \mathrm{H}$ NMR spectrum corresponding to the DMSO protons, two major singlets are present, one for free DMSO at $\delta 2.65$ and one at $\delta 3.38$ for bound DMSO, integrating in a $1: 1$ ratio. A set of weaker intensity resonances is also detected in this region; however, they account for $<5 \%$ of the total integration of the DMSO resonances. The presence of a resonance corresponding to free DMSO in a $1: 1$ ratio with that of bound DMSO indicates that two of the four DMSO ligands formulated for this species, are displaced in $\mathrm{CD}_{3} \mathrm{OD}$. The conductivity of a MeOH solution of isolated $21\left(112 \Omega^{-1} \mathrm{~cm}^{2} \mathrm{~mol}^{-1}\right)$ is in the range for a 1:1 electrolyte, suggesting that one chloride is also dissociated in this solvent. ${ }^{24}$ The $\operatorname{IR}$ data show two strong stretches for $\mathrm{S}=\mathrm{O}$ at 1081 and $1086 \mathrm{~cm}^{-1}$, in the region for S -bound DMSO.

From the ${ }^{1} \mathrm{H}$ NMR data, two possible solution structures (Figures 9a and b) can account for the resonances observed in $\mathrm{CD}_{3} \mathrm{OD}$; these two representations contain equivalent DMSO ligands and equivalent biim rings. Four possible solid state structures (Figure 9c-f) can give rise to the two solution structures (Figures 9a and b); 9e and 9f are preferred, as 9 c and 9 d are formally $\mathrm{Ru}(\mathrm{I} / \mathrm{II})$ spceies. Bimetallic species containing a $\mathrm{Ru}(\mathrm{I})$ metal centre are uncommon and almost exclusively involve a metal-metal bond. ${ }^{27 \mathrm{~b}}$ Precedence for the loss of DMSO and $\mathrm{Cl}^{-}$ligands in solution has been shown with $\mathrm{RuCl}_{2}$ (DMSO) $)_{4}$ which rapidly loses one O-bound DMSO ligand upon dissolution in $\mathrm{D}_{2} \mathrm{O}$, and then slowly loses a $\mathrm{Cl}^{-} .{ }^{29}$
a)

b)

c)

d)

e)

f)

Figure 4.9 Structures (a) and (b) represent possible solution structures for 21, where all DMSO ligands are S -bound and $\mathrm{S}=\mathrm{CD}_{3} \mathrm{OD}$. Structures (c), (d), (e) and (f) represent the four corresponding solid state structures which could give rise to (a) and (b) in $\mathrm{CD}_{3} \mathrm{OD}$; again all DMSO ligands are S-bound.

Similar to the biim system, carrying out a $1: 1$ reaction with $\mathrm{H}_{2} \mathrm{Me}_{2}$ biim and $\mathrm{RuCl}_{2}(\mathrm{DMSO})_{4}$ gives formation of the monomeric $\mathrm{RuCl}_{2}(\mathrm{DMSO})_{2}\left(\mathrm{Me}_{2} \mathrm{biim}\right)$ species (22). ESI-MS and elemental analysis agree with the proposed formulation, and the IR spectrum shows two distinct bands for S-bound DMSO ( $v=1091$ and $1099 \mathrm{~cm}^{-1}$ ).

The ${ }^{1} \mathrm{H}$ NMR spectrum of 22 in $\mathrm{CD}_{3} \mathrm{OD}$ is more complicated than that for the corresponding biim complex, 20, in that 3 resonances are observed for the $H(5)$ protons of the $\mathrm{Me}_{2}$ biim ligand: $\delta 7.65,7.46$, and 7.25 (Figure 4.10b). The integrations at $\delta 7.65$ and 7.25 are the same, while that at $\delta 7.47$ is 1.4 times greater. Three resonances are also observed for the methyl protons of the $\mathrm{Me}_{2}$ biim ligand: $\delta 1.66,1.59$, and 1.58 (Figure 4.10 c ). The integration of the resonances at $\delta 1.58$ and 1.59 are the same, and each of

Figure 4.10 ${ }^{1} \mathrm{H}$ NMR data ( $300 \mathrm{MHz}, 298 \mathrm{~K}$ ) for $\mathrm{Me}_{2}$ biim complexes. a) $\mathrm{H}(5)$ protons of 23 (see text) in $\mathrm{CD}_{3} \mathrm{OD}$. b) $\mathrm{H}(5)$ protons for 22 in $\mathrm{CD}_{3} \mathrm{OD}$; weak resonances for 23 are observed as an impurity. c) Corresponding methyl signals for $\mathrm{Me}_{2}$ biim of $\mathbf{2 2}$ in $\mathrm{CD}_{3} \mathrm{OD}$. Resonances for single isomers are highlited in (b) and (c).
these integrates in a $3: 1$ ratio with those at $\delta 7.65$ and 7.25 , suggesting that these four resonances correspond to a single isomer in which the two rings of the $\mathrm{Me}_{2}$ biim ligand are inequivalent. The remaining two $1: 3$ resonances at $\delta 7.47$ and 1.66 correspond to a second isomer in which the two $\mathrm{Me}_{2} \mathrm{biim}$ rings are equivalent. In the ${ }^{1} \mathrm{H}$ NMR spectrum of 22 there are overlapping signals for bound DMSO between $\delta 3.51-2.23$. The IR data suggest only S-bound DMSO is present; however, from the ${ }^{1} \mathrm{H}$ NMR spectrum, no interpretation of the DMSO proton resonances can be made, other than that there is no evidence for free DMSO.

The conductivity of $\mathbf{2 2}$ in MeOH solution ( $132 \Omega^{-1} \mathrm{~cm}^{2} \mathrm{~mol}^{-1}$ ) is in the range for a 1:1 electrolyte, ${ }^{24}$ suggesting that one $\mathrm{Cl}^{-}$is dissociated, probably from each isomer. The
isomer with the equivalent $\mathrm{Me}_{2}$ biim rings must have trans-chloride and cis-DMSO ligands in the solid state structure, and when one $\mathrm{Cl}^{-}$dissociates and is replaced by MeOH in solution, the equivalence of the two $\mathrm{Me}_{2}$ biim rings is preserved. Two solid state structures can be proposed for the other isomer with inequivalent $\mathrm{Me}_{2} \mathrm{biim}$ rings. The first, a cis- Cl , trans-DMSO species, could produce the observed resonances in the ${ }^{1} \mathrm{H}$ NMR spectrum upon dissociating on chloride in $\mathrm{CD}_{3} \mathrm{OD}$; however, precedence in the literature for such a species with other N -donor ligands could not be found. It is more probable that this species is a cis-Cl, cis-DMSO species as is the case for the analogous biim complex, 20. In the case of the reported $\mathrm{RuCl}_{2}(\mathrm{DMSO})_{2}(2 \mathrm{MeIm})_{2}$, the monodentate analogue of 22, the ${ }^{1} \mathrm{H}$ NMR spectrum (in $\mathrm{CDCl}_{3}$ ) is consistent with an all cisstructure. ${ }^{30}$

When $\mathrm{H}_{2} \mathrm{Me}_{2}$ biim and $\mathrm{RuCl}_{2}(\mathrm{DMSO})_{4}$ are reacted in a $1: 2$ ratio, a bimetallic species analogous to that seen with biim (21) is formed. Elemental analysis and mass spectral data of the isolated complex are consistent with the formulation $\mathrm{Ru}_{2} \mathrm{Cl}_{4}(\mathrm{DMSO})_{4}\left(\mathrm{Me}_{2} \mathrm{biim}\right)$ (23). Although the parent peak is not seen, as for 21, intense signals for $\left[\mathrm{M}^{+}-\mathrm{Cl}\right](785)$, and then fragments for the subsequent loss of 1,2 , and 3

Figure 4.11 Mass spectrum for $\mathrm{Ru}_{2} \mathrm{Cl}_{4}(\mathrm{DMSO})_{4}\left(\mathrm{Me}_{2} \mathrm{biim}\right)$ (23); the most intense group of signals is for $\left[\mathrm{M}^{+}-\mathrm{Cl}-3 \mathrm{DMSO}\right]$, centred at 551 .

DMSO ligands are observed (Figure 4.11), all exhibiting an isotopic splitting pattern consistent with the presence of two Ru atoms in the complex. In the ${ }^{1} \mathrm{H}$ NMR spectrum in $\mathrm{CD}_{3} \mathrm{OD}$, two major resonances are observed for the $\mathrm{H}(5)$ proton at $\delta 7.38$ and 7.33 (Figure 4.10 a), that at $\delta 7.38$ being roughly twice the size of that at $\delta 7.33$; this suggests the presence of two isomers with equivalent $\mathrm{Me}_{2}$ biim rings. There is also a pair of $1: 1$ singlets at $\delta 7.47$ and 7.46 , implying the presence of one isomer with inequivalent $\mathrm{Me}_{2} \mathrm{biim}$ rings. Between $\delta 3.55$ and 2.54, numerous overlapping and unresolved resonances are observed for the Me resonances of the DMSO and $\mathrm{Me}_{2}$ biim ligands, including an intense resonance for free DMSO. As for 21, the conductivity of 23 in MeOH solution ( $97 \Omega^{-1} \mathrm{~cm}^{2} \mathrm{~mol}^{-1}$ ) is in the range for a $1: 1$ electrolyte, ${ }^{24}$ suggesting replacement of a terminal Cl ligand by MeOH .

### 4.5 Complexes Synthesized from $\mathrm{Ru}(\mathrm{ma})_{3}$

In Chapter 3, the synthesis and characterization of $\mathrm{Ru}(\mathrm{III})$ complexes of the type $\left[\mathrm{Ru}(\mathrm{ma})_{2}(\mathrm{~L})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$, where L is an N -bound imidazole or triazole derivative, were presented. With the same experimental procedure used for 14 (Section 3.3.5), analogous complexes of the type $\left[\mathrm{Ru}(\mathrm{ma})_{2}(\mathrm{~L})\right] \mathrm{CF}_{3} \mathrm{SO}_{3} \cdot 2 \mathrm{H}_{2} \mathrm{O}$, where $\mathrm{L}=$ biim (24) or Me $\mathrm{Me}_{2}$ biim (25), were synthesized. These were characterized by elemental analysis, mass spectrometry, and $\operatorname{IR}$ and NMR spectroscopies. The ${ }^{\mathrm{l}} \mathrm{H}$ NMR spectrum of 24 in $\mathrm{CDCl}_{3}$ (Figure 4.12a) shows a single resonance for the maltolato Me groups. As the biim rings are "locked" in a cis-configuration, the maltolato ligands must be coordinated so that the "same type" oxygen from each maltolato is trans to biim (Figure 4.13).

In the corresponding ${ }^{1} \mathrm{H}$ NMR spectrum of $\mathbf{2 5}$, two resonances are detected for the maltolato Me groups as well as two resonances for the $\mathrm{Me}_{2} \mathrm{biim}$ Me groups. This is due either to inequivalent oxygen atoms bound trans to $\mathrm{Me}_{2}$ biim (Figure 4.14b), or to the complex existing in solution as a combination of two different isomers with equivalent oxygen atoms bound trans to $\mathrm{Me}_{2}$ biim (Figure 4.14b and c). Although the integrations of signals in paramagnetic ${ }^{1} \mathrm{H}$ NMR spectra are generally poor, the near equal intensities and
peak widths of the two maltolato Me signals might indicate that they are for a single species, thus favouring the structure in Figure 4.14a.

Figure 4.12 ${ }^{\mathrm{I}} \mathrm{H}$ NMR spectra of 24 and 25. a) ${ }^{1} \mathrm{H}$ NMR spectrum ( $300 \mathrm{MHz}, 298 \mathrm{~K}$ ) of 24 in $\mathrm{CDCl}_{3}$. b) ${ }^{1} \mathrm{H}$ NMR spectrum ( $300 \mathrm{MHz}, 298 \mathrm{~K}$ ) of $\mathbf{2 5}$ in $\mathrm{CDCl}_{3}$.

Figure 4.13 Proposed structure for the cation of 24.

(a)

(b)

(c)

Figure 4.14 Three possible structures for the cation of $\mathbf{2 5}$.

The elemental analyses for both complexes give formulations with two hydrated $\mathrm{H}_{2} \mathrm{O}$ molecules. The IR spectra show strong, broad bands at 3514 and $3550 \mathrm{~cm}^{-1}$ for $\mathrm{O}-\mathrm{H}$ for 24 and 25 , respectively, consistent with the presence of $\mathrm{H}_{2} \mathrm{O}$ in the solids. The cyclic voltammograms of the complexes in MeCN reveal markedly more positive reduction potentials than for the analogous bis(imidazole) complexes ( $\mathbf{7}$ and 10, Table 4.1). The difference in cis/trans geometry of the bis(imidazole) and biimidazole complexes can not account for such a large difference in potential; however, the more conjugated $\pi$-system of the biimidazole ligands may make these ligands better $\pi$-acceptors and thus increase the reduction potentials for $\mathbf{2 4}$ and $\mathbf{2 5}$.

Table 4.1 $\mathrm{Ru}(\mathrm{III} / \mathrm{I})$ reduction potentials for the biimidazole complexes 24 and 25, compared with those for $\mathbf{7}$ and $\mathbf{1 0}$.

| Complex | $\mathrm{Ru}(\mathrm{III} / \mathrm{II})$ Reduction Potential in MeCN vs. |
| :--- | :---: |
| $\mathrm{SCE}(\mathrm{mV})$ |  |

### 4.6 Complexes Synthesized from [Ru(DMF) $]_{6}\left(\mathrm{CF}_{3} \mathrm{SO}_{3}\right)_{3}$

$\left[\mathrm{Ru}(\mathrm{DMF})_{6}\right]\left(\mathrm{CF}_{3} \mathrm{SO}_{3}\right)_{3}$ has been previously used in this group as a precursor for the synthesis of $\mathrm{Ru}(\mathrm{II})$ hexakis(imidazole) complexes. ${ }^{31}$ The same general synthetic
procedure with MeOH as solvent was employed in the synthesis of the analogous complexes $\left[\mathrm{Ru}(\mathrm{L})_{3}\right]\left(\mathrm{CF}_{3} \mathrm{SO}_{3}\right)_{2}$, where $\mathrm{L}=\operatorname{biim}$ (26) and $\mathrm{Me}_{2}$ biim (27), which were isolated in 72 and $83 \%$ yield, respectively. Four equivalents of ligand are required for the syntheses, whereby one equivalent of $\mathrm{H}_{2}$ biim or $\mathrm{H}_{2} \mathrm{Me}_{2}$ biim reduces the Ru centre (III $\rightarrow$ II). ${ }^{32}$ Although MeOH can also act as a reducing agent, ${ }^{33}$ the same synthetic reaction with $\mathrm{H}_{2}$ biim performed in situ in $\mathrm{CD}_{3} \mathrm{OD}$ showed no trace of free $\mathrm{H}_{2}$ biim after 12 h by ${ }^{1} \mathrm{H}$ NMR spectroscopy, but instead the spectrum of the product solution showed two singlets at $\delta 8.92$ and 7.84 , not present in the spectrum for the isolated complex, 26. These resonances may be due to a bis-biimidazole species (such as that shown in Figure 4.15), resulting from one equivalent of $\mathrm{H}_{2}$ biim being oxidized by the $\mathrm{Ru}(\mathrm{III})$. This type of $\mathrm{Ru}(\mathrm{III}) \rightarrow \mathrm{Ru}($ II $)$ reduction in the presence of excess Im has been reported to occur in water at r.t. over several days. ${ }^{32}$ For both 26 and 27 , the mass spectra clearly show both the $\mathrm{Ru}(\mathrm{L})_{3}{ }^{+}$peaks $\left(\mathrm{M}^{+}\right.$for $\mathbf{2 6}$ and 27 is defined as $\left[\mathrm{Ru}(\mathrm{L})_{3}\right]\left[\mathrm{CF}_{3} \mathrm{SO}_{3}\right]_{2}$, see Sections 4.9.7 and 4.9.8) as well as the $\left[\mathrm{Ru}(\mathrm{L})_{3}\right]\left[\mathrm{CF}_{3} \mathrm{SO}_{3}\right]^{+}$peaks ( $\mathrm{L}=$ biim or $\mathrm{Me}_{2}$ biim, respectively). The ${ }^{1} \mathrm{H}$ NMR spectrum of the $\mathbf{2 6}$ displays 2 equal intensity singlets at $\delta 8.37$ for $\mathrm{H}(2)$ and 7.62 for $\mathrm{H}(5)$. In the corresponding ${ }^{1} \mathrm{H}$ NMR spectrum of 27 , two resonances at $\delta 7.43$ for $\mathrm{H}(5)$ and 2.54 for the Me-group, integrating for 1 and 3 protons, respectively, are detected.

Figure 4.15 Possible structure for a bis-biimidazole species, from reduction of the Ru centre.

### 4.7 Complexes Synthesized from $\mathrm{RuCl}_{3} \cdot \mathbf{3} \mathrm{H}_{2} \mathrm{O}$

$\mathrm{RuCl}_{3} \cdot 3 \mathrm{H}_{2} \mathrm{O}$ was also used as a precursor for the synthesis of Ru -biim and Ru $\mathrm{Me}_{2} \mathrm{biim}$ complexes; these were synthesized via the 'Ru blue' solution, formed upon reduction of $\mathrm{RuCl}_{3} \cdot 3 \mathrm{H}_{2} \mathrm{O}$ by $\mathrm{H}_{2}$ in MeOH . ${ }^{34}$ Addition of 2 equivalents of $\mathrm{H}_{2}$ biim to such a solution gives a complex formulated as $\left[\mathrm{Ru}(\mathrm{Hbiim})_{2} \mathrm{Cl}_{2}\right] \mathrm{Cl}_{2}(\mathbf{2 8})$, which was isolated as a brown precipitate from a $\mathrm{MeOH} /$ acetone solution and characterized by ${ }^{1} \mathrm{H}$ NMR spectroscopy and ESI-MS. Only two broad singlets at $\delta 8.59$ and 7.52 are observed in

Figure 4.16 Molecular structure for 28.
the ${ }^{1} \mathrm{H}$ NMR spectrum in $\mathrm{D}_{2} \mathrm{O}$, suggesting that the biim ligands are trans with 4 chemically equivalent heterocyclic rings. The two additional protons in the complex presumably exchange mutually in solution, thus broadening the proton resonances of $\mathrm{H}(2)$ and $\mathrm{H}(5)$. A potentiometric titration of a solution of 28 in $\mathrm{H}_{2} \mathrm{O}$ at r.t. with 0.01 M $\mathrm{AgNO}_{3}$ solution confirmed the presence of the two non-coordinated chlorides, the solution conductivity increased sharply after 2 equivalents of $\mathrm{AgNO}_{3}$ had been added, suggesting that two equivalents of chloride had been titrated. MS on the resulting solution, after the titration was completed, revealed that the complex was still intact ( $\mathrm{M}^{+}$ at 440) with two $\mathrm{Cl}^{-}$bound. Titration of a solution of 28 in $\mathrm{H}_{2} \mathrm{O}$ with 0.01 M NaOH gave two equivalence points for the two titratable protons with $\mathrm{pK}_{\mathrm{a}}$ values of 7.7 and 8.5. The conductivity of an aqueous solution of 28 was $265 \Omega^{-1} \mathrm{~cm}^{2} \mathrm{~mol}^{-1}$, in the range for a 2:1 electrolyte. ${ }^{35}$

The corresponding "Ru blue" reaction with $\mathrm{H}_{2} \mathrm{Me}_{2}$ biim in place of $\mathrm{H}_{2}$ biim gave a product consistent with the formulation for $\left[\mathrm{Ru}\left(\mathrm{HMe}_{2} \mathrm{biim}\right)\left(\mathrm{Me}_{2} \mathrm{biim}\right)_{2}\right] \mathrm{Cl}_{3}$ (29). Again, only two broad signals are observed in the ${ }^{1} \mathrm{H}$ NMR spectrum in $\mathrm{D}_{2} \mathrm{O}$, one for the $\mathrm{H}(5)$
protons, and one for the Me protons, consistent with three equivalent $\mathrm{Me}_{2} \mathrm{biim}$ ligands with the extra proton presumably exchanging between all 3 of them. Titration of a solution of 29 in $\mathrm{H}_{2} \mathrm{O}$ with $\mathrm{AgNO}_{3}$ confirmed the presence of 3 unbound $\mathrm{Cl}^{-}$ions while titration with NaOH showed that there was one titratable proton with a $\mathrm{pK}_{\mathrm{a}}$ of 8.8 . The conductivity of 29 in $\mathrm{H}_{2} \mathrm{O}\left(385 \Omega^{-1} \mathrm{~cm}^{2} \mathrm{~mol}^{-1}\right)$ is in the range for a $3: 1$ electrolyte. ${ }^{35}$ Unlike 28 where two biim ligands can adopt a trans-configuration, $2 \mathrm{Me}_{2}$ biim ligands are unlikely to be mutually trans due to the steric hindrance of the 2-methyl groups, and this results in the ready formation of the all-cis tris-substituted product.

### 4.8 Experimental Preparation of Biimidazoles

### 4.8.1 Sources of Materials

The sources of solvents, some reagents and Ru precursors are reported in Chapter 2. $\mathrm{Pd}\left(\mathrm{PPh}_{3}\right)_{4}$ was prepared according to a literature procedure. ${ }^{9} \mathrm{PdCl}_{2}$ was obtained from Colonial Metals Inc. $\mathrm{I}_{2}, \mathrm{NEt}_{3}, \mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3}$ and $\mathrm{Na}_{2} \mathrm{SO}_{3}$ (not listed in Chapter 2) were all purchased from Fisher Scientific.

### 4.8.2 2,4,5-Triiodoimidazole

This compound was synthesized according to literature procedures. ${ }^{36-39}$ To a solution of $\mathrm{I}_{2}(112.0 \mathrm{~g}, 441 \mathrm{mmol})$ in $\mathrm{CHCl}_{3}(400 \mathrm{~mL})$ was added $\operatorname{Im}(10.0 \mathrm{~g}, 147 \mathrm{mmol})$ and $2 \mathrm{M} \mathrm{NaOH}(400 \mathrm{~mL})$. This mixture formed a two-phase system with the organic phase containing the $\mathrm{I}_{2}$ on the bottom, and the top aqueous phase being colourless. The mixture was stirred for 3 h at r.t. after which time the bottom phase had become colourless and the top phase had turned pink. The phases were separated and the organic phase was discarded. To the aqueous phase was added $\mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3}(50.0 \mathrm{~g})$ to prevent colouration of the product, before the aqueous phase was neutralized to pH 7.0 with AcOH . The resulting white precipitate was collected, washed with cold water ( $2 \times 10$ $\mathrm{mL})$ and dried at $80{ }^{\circ} \mathrm{C}$ for 16 h . Yield: $46.42 \mathrm{~g}(70 \%)$. FAB-MS: $446\left(\mathrm{M}^{+}\right), 320\left(\mathrm{M}^{+}-\right.$ I), 193 ( $\mathrm{M}^{+}-2 \mathrm{I}$ ).

### 4.8.3 4(5)-Iodoimidazole

This compound was synthesized from a modified literature procedure. ${ }^{36}$ To a solution of $\mathrm{Na}_{2} \mathrm{SO}_{3}(70.0 \mathrm{~g}, 555 \mathrm{mmol})$ in $30 \%$ aq. $\mathrm{EtOH}(1.0 \mathrm{~L}), 2,4,5$-triiodoimidazole $(30.0 \mathrm{~g}, 67.3 \mathrm{mmol})$ was added. The mixture was heated at $50^{\circ} \mathrm{C}$ for 1 h at which time the solid had completely dissolved affording a yellow solution that was refluxed for 24 h . The condenser was then removed and the solution concentrated until a precipitate started to form. The flask was then immediately removed from the heating mantel and allowed to cool slowly to r.t. The resulting pale yellow crystals were removed by filtration and dried under vacuum for 24 h . Yield: $8.42 \mathrm{~g}(64 \%) .{ }^{1} \mathrm{H}$ NMR (acetone- $d_{6}$ ): $\delta 10.20(\mathrm{br} \mathrm{s}$, $\left.1 \mathrm{H}, \mathrm{Im}-\mathrm{H}_{1}\right), 7.80\left(\mathrm{~s}, 1 \mathrm{H}, \operatorname{Im}-\mathrm{H}_{2}\right), 7.28\left(\mathrm{~s}, 1 \mathrm{H}, \mathrm{Im}-\mathrm{H}_{5}\right)$. FAB-MS: $194\left(\mathrm{M}^{+}\right), 67\left(\mathrm{M}^{+}-\mathrm{I}\right)$. Anal. Calcd for $\mathrm{C}_{3} \mathrm{H}_{3} \mathrm{~N}_{2} \mathrm{I}$ : C, 18.56; H, 1.55; N, 14.43. Found: C, 18.52; H, 1.61 ; N, 14.21 .

### 4.8.4 4-Iodo-1-(triphenylmethyl)imidazole

This compound was synthesized from a literature procedure. ${ }^{36}$ To a solution of 4iodoimidazole ( $4.00 \mathrm{~g}, 20.6 \mathrm{mmol}$ ) in DMF ( 35 mL ) was added chlorotriphenylmethane ( $5.75 \mathrm{~g}, 20.6 \mathrm{mmol}$ ). The solution was degassed for 10 min and then stirred at r.t. for 1 h under $\mathrm{N}_{2}$. To this solution was then added $\mathrm{NEt}_{3}(2.30 \mathrm{~g}, 22.7 \mathrm{mmol})$ and the resulting mixture was stirred for 24 h . The mixture was then poured into an ice slurry ( 150 mL ) and the precipitate was collected via filtration. The solid was dried under vacuum at 78 ${ }^{\circ} \mathrm{C}$ for 24 h . Yield: $6.23 \mathrm{~g}(69 \%) .{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right)$ : $\delta 7.37-7.29\left(\mathrm{~m}, 10 \mathrm{H}, \mathrm{Im}-\mathrm{H}_{2}\right.$ and $\mathrm{ArH}), 7.14-7.09(\mathrm{~m}, 6 \mathrm{H}, \mathrm{ArH}), 6.92\left(\mathrm{~d}, 1 \mathrm{H}, \mathrm{Im}-\mathrm{H}_{5}\right)$. FAB-MS: $436\left(\mathrm{M}^{+}\right), 243\left(\mathrm{CPh}_{3}\right)$, $194\left(\mathrm{M}^{+}-\mathrm{CPh}_{3}\right)$. Anal. Calcd for $\mathrm{C}_{22} \mathrm{H}_{17} \mathrm{~N}_{2} \mathrm{I}: \mathrm{C}, 60.55 ; \mathrm{H}, 3.90 ; \mathrm{N}, 6.42$. Found: C , $60.69 ; \mathrm{H}, 4.11 ; \mathrm{N}, 6.18$. The ${ }^{\prime} \mathrm{H}$ NMR data for this compound agree with those reported. ${ }^{36}$

### 4.8.5 1,1'-Bis(triphenylmethyl)-4,4'-biimidazole

This compound and the following six compounds were synthesized via modified literature procedures. ${ }^{5}$ A solution of 4-iodo-1-(triphenylmethyl)imidazole ( $4.00 \mathrm{~g}, 9.17$ $\mathrm{mmol})$ in DMF ( 15 mL ) was degassed with Ar for 10 min . To this solution was added $\operatorname{Pd}\left(\mathrm{PPh}_{3}\right)_{4}(450 \mathrm{mg}, 0.39 \mathrm{mmol})$ and $\mathrm{NEt}_{3}(1.96 \mathrm{~g}, 18.4 \mathrm{mmol})$. The flask was then
wrapped in foil and heated to $120^{\circ} \mathrm{C}$ for 48 h in the dark. The solution was cooled to r.t., and the resulting precipitate was collected by filtration, rinsed with acetone ( $3 \times 5$ mL ), and dried under vacuum for 24 h at $78^{\circ} \mathrm{C}$. Yield: $2.21 \mathrm{~g}(78 \%) .{ }^{\mathrm{l}} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right)$ : $\delta 7.37$ (d, 2H, $H_{2,2^{2}-\mathrm{biim}}$ ), 7.32-7.29 (m, 18H, ArH), 7.27 (d, 2H, $H_{5,5}$-biim), 7.20-7.17 $(\mathrm{m}, 12 \mathrm{H}, \mathrm{Ar} H)$. FAB-MS: $618\left(\mathrm{M}^{+}\right), 243\left(\mathrm{CPh}_{3}\right)$. Anal. Calcd for $\mathrm{C}_{44} \mathrm{H}_{34} \mathrm{~N}_{4}: \mathrm{C}, 85.43$; H, 5.50; N, 9.06. Found: C, 85.61; H, 5.43; N, 8.75. The ${ }^{\mathrm{l}} \mathrm{H}$ NMR and MS characterization data for this compound and for the next six compounds agree with those reported. ${ }^{5}$

### 4.8.6 4,4'-Biimidazolium trifluoroacetate ( $\mathbf{H}_{\mathbf{2}} \mathbf{b i i m}$ )

1,1'-Bis(triphenylmethyl)-4,4'-biimidazole ( $2.00 \mathrm{~g}, 3.23 \mathrm{mmol}$ ) was dissolved in $50 \% \mathrm{CF}_{3} \mathrm{CO}_{2} \mathrm{H} / \mathrm{H}_{2} \mathrm{O}(50 \mathrm{~mL})$ and the solution was stirred at r.t. for 12 h . The resulting white precipitate $\left(\mathrm{CPh}_{3} \mathrm{OH}\right)$ was then removed by filtration and the yellow filtrate was evaporated under vacuum to yield a bright yellow oil. Addition of MeCN ( 2.0 mL ) yielded a white solid that was collected, rinsed with acetone ( $3 \times 5 \mathrm{~mL}$ ) and dried under vacuum at $78{ }^{\circ} \mathrm{C}$ for 24 h . Yield: $0.96 \mathrm{~g}(82 \%)$. ${ }^{1} \mathrm{H}$ NMR ( $\left.\mathrm{CD}_{3} \mathrm{OD}\right): \delta 8.74\left(\mathrm{~s}, 2 \mathrm{H}, \mathrm{H}_{2,22^{\prime}}\right.$ biim), 7.79 (s, $2 \mathrm{H}, \mathrm{H}_{5,5} 5^{-}$-biim). ESI-MS: $135\left(\mathrm{M}^{+}\right)$. Anal. Calcd for $\mathrm{C}_{10} \mathrm{H}_{8} \mathrm{~N}_{4} \mathrm{~F}_{6} \mathrm{O}_{4}$ : C, 33.15; H, 2.21; N, 15.47. Found: C, 33.24; H, 2.12; N, 15.68.

### 4.8.7 4,5,-Diiodo-2-methylimidazole

To a solution of $2 \mathrm{MeIm}(10.0 \mathrm{~g}, 122 \mathrm{mmol})$ in $2 \mathrm{M} \mathrm{NaOH}(300 \mathrm{~mL})$ was added $\mathrm{CHCl}_{3}(300 \mathrm{~mL}) . \mathrm{I}_{2}(62.0 \mathrm{~g}, 244 \mathrm{mmol})$ was then added to this mixture slowly over 20 min, adding 5 g at a time and waiting until it had completely dissolved before adding more. Adding the $I_{2}$ too quickly led to the formation of a brown foam, from which the final product could not be separated. The two-phase system was then stirred for an additional 3 h at which time the lower phase had become colourless. The phases were separated and the aqueous phase neutralized according to the procedure described in Section 4.8.2. Yield: $28.10 \mathrm{~g}(69 \%) .{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta 10.72$ (br s, $\left.\operatorname{Im}-H_{1}\right), 2.48(\mathrm{~s}$, Im- $\mathrm{CH}_{3}$ ). FAB: $335\left(\mathrm{M}^{+}\right), 209\left(\mathrm{M}^{+}-\mathrm{I}\right)$.

### 4.8.8 4(5)-Iodo-2-methylimidazole

4,5,-Diiodo-2-methylimidazole ( $20.0 \mathrm{~g}, 59.9 \mathrm{mmol}$ ) was dissolved in 700 mL $\mathrm{H}_{2} \mathrm{O}$. To this solution was added $\mathrm{Na}_{2} \mathrm{SO}_{3}(60.0 \mathrm{~g}, 476 \mathrm{mmol})$ and $\mathrm{EtOH}(300 \mathrm{~mL})$. This mixture was heated for 1 h at $50^{\circ} \mathrm{C}$ until the sulfite had completely dissolved. The yellow solution was then refluxed for 24 h , cooled to r.t., and 500 mL of EtOH were added. The resulting white precipitate (sodium salts) was removed by filtration and the filtrate was concentrated until a fine precipitate started to form. The filtrate was then cooled and the resulting yellow crystals were collected, washed with cold $\mathrm{H}_{2} \mathrm{O}(2 \times 5 \mathrm{~mL})$ and dried at $78{ }^{\circ} \mathrm{C}$ for 24 h . Yield: $6.82 \mathrm{~g}(55 \%) .{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta 11.08(\mathrm{br} \mathrm{s}, 1 \mathrm{H}$, $\left.\operatorname{Im}-H_{1}\right), \delta 7.08\left(\mathrm{~s}, 1 \mathrm{H}, \operatorname{Im}-H_{5}\right), 2.44\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{Im}-\mathrm{CH}_{3}\right) . \mathrm{FAB}: 209\left(\mathrm{M}^{+}\right)$.

### 4.8.9 4-Iodo-2-methyl-1-(triphenylmethyl)imidazole

4(5)-Iodo-2-methylimidazole ( $4.69 \mathrm{~g}, 22.5 \mathrm{mmol}$ ) was added to a solution of chlorotriphenylmethane ( $4.18 \mathrm{~g}, 15.0 \mathrm{mmol}$ ) in DMF ( 40.0 mL ). Under $1 \mathrm{~atm} \mathrm{~N}_{2}, \mathrm{NEt}_{3}$ $(1.95 \mathrm{~g}, 19.2 \mathrm{mmol})$ was added and the solution was stirred at r.t. for 24 h . The mixture was then poured onto an ice slurry $(150 \mathrm{~mL})$ and the resulting precipitate was collected and dried under vacuum for 24 h at $78{ }^{\circ} \mathrm{C}$. Yield: $4.52 \mathrm{~g}(67 \%) .{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right)$ : ס7.36-7.33 (m, 9H, ArH), 7.14-7.09 (m, 6H, ArH), 6.75 (s, 1H, Im- $H_{5}$ ), 1.58 ( $\mathrm{s}, 3 \mathrm{H}, \mathrm{Im}-$ $\left.\mathrm{CH}_{3}\right)$. FAB: $450\left(\mathrm{M}^{+}\right), 243\left(\mathrm{CPh}_{3}\right), 209\left(\mathrm{M}^{+}-\mathrm{CPh}_{3}\right)$. Anal. Calcd for $\mathrm{C}_{23} \mathrm{H}_{19} \mathrm{~N}_{2} \mathrm{I}: \mathrm{C}$, 61.33; H, 4.22; N, 6.22. Found: C, 61.25; H, 4.17; N, 6.02.

### 4.8.10 2,2'-Dimethyl -1,1'-bis(triphenylmethyl)-4,4'-biimidazole

4-Iodo-2-methyl-1-triphenylmethylimidazole( $4.00 \mathrm{~g}, 8.89 \mathrm{mmol}$ ) was dissolved in DMF ( 15 mL ), and the solution was degassed with Ar for 10 min . To this was added $\operatorname{Pd}\left(\mathrm{PPh}_{3}\right)_{4}(550 \mathrm{mg}, 0.440 \mathrm{mmol})$ and $\mathrm{NEt}_{3}(1.80 \mathrm{~g}, 17.8 \mathrm{mmol})$. The flask was then sealed under $\mathrm{N}_{2}$ and wrapped in foil to exclude all light, and the reaction mixture then heated at $120^{\circ} \mathrm{C}$ for 48 h . The flask was then cooled to r.t. and the resulting precipitate was collected, washed with acetone ( $3 \times 5 \mathrm{~mL}$ ), and dried under vacuum at $78^{\circ} \mathrm{C}$ for 24 h. Yield: $1.97 \mathrm{~g}(69 \%) .{ }^{1} \mathrm{H} \operatorname{NMR}\left(\mathrm{CDCl}_{3}\right): \delta 7.31-7.29(\mathrm{~m}, 18 \mathrm{H}, \mathrm{ArH}), 7.22\left(\mathrm{~s}, 2 \mathrm{H}, \mathrm{H}_{5,55^{\prime}}\right.$ $\mathrm{Me}_{2} \mathrm{biim}$ ), $7.17-7.15$ (m, 12H, ArH ), 1.60 ( $\left.\mathrm{s}, 6 \mathrm{H}, \mathrm{CH}_{3}-\mathrm{Me}_{2} \mathrm{biim}\right)$. LSIMS: $647\left(\mathrm{M}^{+}\right), 243$ N, 8.48.

### 4.8.11 2,2'-Dimethyl-4,4'-biimidazolium trifluoroacetate ( $\mathbf{H}_{2} \mathbf{M e}_{2}$ biim)

2,2'-Dimethyl-1,1'-bis(triphenylmethyl)-4,4'-biimidazole ( $1.90 \mathrm{~g}, 2.94 \mathrm{mmol}$ ) was suspended in $60 \% \mathrm{CF}_{3} \mathrm{CO}_{2} \mathrm{H} / \mathrm{H}_{2} \mathrm{O}(50 \mathrm{~mL})$, and the mixture was then refluxed for 6 h and cooled to r.t., when the resulting precipitate was removed by filtration. The filtrate was evaporated to give a yellow oil. MeCN ( 3 mL ) was added affording a white precipitate that was collected, washed with acetone ( $3 \times 5 \mathrm{~mL}$ ), and dried under vacuum for 24 h at $78{ }^{\circ} \mathrm{C}$. Yield: $0.89 \mathrm{~g}(78 \%) .{ }^{1} \mathrm{H}$ NMR ( $\left.\mathrm{CD}_{3} \mathrm{OD}\right): \delta 7.65$ (s, $2 \mathrm{H}, H_{5,5}-\mathrm{Me}_{2} \mathrm{biim}$ ), 2.72 (s, 6H, $\mathrm{CH}_{3}-\mathrm{Me}_{2}$ biim). ESI-MS: $163\left(\mathrm{M}^{+}\right)$. Anal. Calcd for $\mathrm{C}_{12} \mathrm{H}_{12} \mathrm{~N}_{4} \mathrm{~F}_{6} \mathrm{O}_{4}$ : C, 36.92; H, 3.08; N, 14.36. Found: C, 37.19; H, 2.98; N, 14.38.

### 4.9 Experimental Syntheses of Complexes

### 4.9.1 cis- $\mathrm{RuCl}_{2}(\mathrm{DMSO})_{2}$ (biim) (20)

To a yellow solution of $\mathrm{RuCl}_{2}(\mathrm{DMSO})_{4}(0.070 \mathrm{~g}, 0.15 \mathrm{mmol})$ in $\mathrm{MeOH}(10$ $\mathrm{mL}), \mathrm{H}_{2}$ biim was added ( $0.054 \mathrm{~g}, 0.15 \mathrm{mmol}$ ) under $\mathrm{N}_{2}$ and the mixture refluxed for 4 h . The solvent was then reduced in volume to $\sim 1 \mathrm{~mL}$, followed by the addition of 10 mL of acetone that yielded a yellow precipitate that was collected, washed with acetone ( $2 \times 5$ $\mathrm{mL})$, and dried in vacuo. Yield: $0.059 \mathrm{~g}(88 \%) .{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CD}_{3} \mathrm{OD}\right): \delta 8.39,8.37(\mathrm{~s}, 2 \mathrm{H}$, $H_{2,2^{\prime}}$-biim), 7.72, 7.67 (s, 2H, $H_{5,5}$-biim), $3.49\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{CH}_{3} \mathrm{SOCH}_{3}\right.$ ), 3.23 ( $\mathrm{s}, 3 \mathrm{H}$, $\mathrm{CH}_{3} \mathrm{SOCH}_{3}$ ), 3.01 ( $\mathrm{s}, 3 \mathrm{H}, \mathrm{CH}_{3} \mathrm{SOCH}_{3}$ ), 2.29 ( $\mathrm{s}, 3 \mathrm{H}, \mathrm{CH}_{3} \mathrm{SOCH}_{3}$ ). IR ( KBr pellet): $v$ 3451 (s, N-H), 1067 (s, S=O), 1020 (m). ESI-MS (MeOH): 463 ( $\mathrm{M}^{+}$), 427 ( $\mathrm{M}^{+}$- Cl), 349 $\left(\mathrm{M}^{+}-\mathrm{Cl}-\mathrm{DMSO}\right) . \Lambda_{\mathrm{M}}(\mathrm{MeOH})=127 \Omega^{-1} \mathrm{~cm}^{2} \mathrm{~mol}^{-1}$. Anal. Calcd for $\mathrm{C}_{10} \mathrm{H}_{18} \mathrm{Cl}_{2} \mathrm{~N}_{4} \mathrm{O}_{2} \mathrm{~S}_{2} \mathrm{Ru}$ : C, 25.87 ; H, 3.90; N, 12.12. Found: C, 25.67 ; H, $3.98 ; \mathrm{N}, 11.99$.

### 4.9.2 $\quad \mathrm{Ru}_{2} \mathrm{Cl}_{4}(\mathrm{DMSO})_{4}(\mathrm{biim})(21)$

This complex was synthesized following the procedure outlined in Section 4.9.1, but using $\mathrm{H}_{2}$ biim ( $0.026 \mathrm{~g}, 0.074 \mathrm{mmol}$ ) and $\mathrm{RuCl}_{2}(\mathrm{DMSO})_{4}(0.071 \mathrm{~g}, 0.15 \mathrm{mmol})$. Yield: $0.042 \mathrm{~g}(73 \%) .{ }^{\mathrm{I}} \mathrm{H}$ NMR $\left(\mathrm{CD}_{3} \mathrm{OD}\right): \delta 8.55\left(\mathrm{~s}, 2 \mathrm{H}, H_{2,2^{\prime}}\right.$-biim), $7.48\left(\mathrm{~s}, 2 \mathrm{H}, H_{5,5{ }^{\prime}-}\right.$
biim), 3.46 ( $\mathrm{s}, 6 \mathrm{H}, \mathrm{CH}_{3} \mathrm{SOCH}_{3}$ ), 2.65 ( $\mathrm{s}, 6 \mathrm{H}$, free DMSO ). IR ( KBr pellet): v 3449 (br s, N-H), 1086 (s, S=O), 1081 ( $\mathrm{s}, \mathrm{S}=\mathrm{O}$ ), 1013 (m). ESI-MS ( MeOH ): 757 ( $\left.\mathrm{M}^{+}-\mathrm{Cl}\right), 679\left(\mathrm{M}^{+}\right.$ - Cl - DMSO). $\Lambda_{\mathrm{M}}(\mathrm{MeOH})=112 \Omega^{-1} \mathrm{~cm}^{2} \mathrm{~mol}^{-1}$. Anal. Calcd for $\mathrm{C}_{14} \mathrm{H}_{30} \mathrm{Cl}_{4} \mathrm{~N}_{4} \mathrm{O}_{4} \mathrm{~S}_{4} \mathrm{Ru}_{2}: \mathrm{C}$, 21.27 ; H, 3.80; N, 7.09. Found: C, 21.36; H, 4.00; N, 7.51.

### 4.9.3 $\quad \mathrm{RuCl}_{2}(\mathrm{DMSO})_{2}\left(\mathrm{Me}_{2} \mathrm{biim}\right)(22)$

This complex was synthesized following the procedure outlined in Section 4.9.1, but using $\mathrm{H}_{2} \mathrm{Me}_{2}$ biim ( $0.058 \mathrm{~g}, 0.15 \mathrm{mmol}$ ) and $\mathrm{RuCl}_{2}(\mathrm{DMSO})_{4}(0.072 \mathrm{~g}, 0.15 \mathrm{mmol})$. Yield: $0.064 \mathrm{~g}(90 \%) .{ }^{1} \mathrm{H} \operatorname{NMR}\left(\mathrm{CD}_{3} \mathrm{OD}\right): \delta 7.65,7.47,7.25\left(\mathrm{~s}, 2 \mathrm{H}, H_{5,5}-\mathrm{Me}_{2} \mathrm{biim}\right)$, 3.54-3.32, 3.25-2.73, 2.32 ( $\mathrm{s}, 12 \mathrm{H}, \mathrm{CH}_{3} \mathrm{SOCH}_{3}$ ), $1.66,1.59,1.58$ ( $\mathrm{s}, 6 \mathrm{H}, \mathrm{CH}_{3}-\mathrm{Me}_{2} \mathrm{biim}$ ). IR ( KBr pellet): v 3455 (N-H), 1420 ( s ), 1091 ( $\mathrm{s}, \mathrm{S}=\mathrm{O}$ ), 1099 ( $\mathrm{s}, \mathrm{S}=\mathrm{O}$ ), 1014 (m). ESIMS (MeOH): $491\left(\mathrm{M}^{+}\right), 455\left(\mathrm{M}^{+}-\mathrm{Cl}\right), 377\left(\mathrm{M}^{+}-\mathrm{Cl}-\mathrm{DMSO}\right) . \Lambda_{\mathrm{M}}(\mathrm{MeOH})=132 \Omega^{-}$ ${ }^{1} \mathrm{~cm}^{2} \mathrm{~mol}^{-1}$. Anal. Calcd for $\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{Cl}_{2} \mathrm{~N}_{4} \mathrm{O}_{2} \mathrm{~S}_{2} \mathrm{Ru}: \mathrm{C}, 29.39 ; \mathrm{H}, 4.49 ; \mathrm{N}, 11.43$. Found: C, 29.58; H, 4.64; N, 11.82.

### 4.9.4 $\quad \mathrm{Ru}_{2} \mathrm{Cl}_{4}(\mathrm{DMSO})_{4}\left(\mathrm{Me}_{2} \mathrm{biim}\right)$ (23)

This complex was synthesized following the procedure outlined in Section 4.9.1, but using $\mathrm{H}_{2} \mathrm{Me}_{2} \operatorname{biim}(0.029 \mathrm{~g}, 0.074 \mathrm{mmol})$ and $\mathrm{RuCl}_{2}(\mathrm{DMSO})_{4}(0.070 \mathrm{~g}, 0.15 \mathrm{mmol})$. Yield: $0.049 \mathrm{~g}(81 \%) .{ }^{1} \mathrm{H} \operatorname{NMR}\left(\mathrm{CD}_{3} \mathrm{OD}\right): \delta 7.47,7.46,7.38,7.33$ ( $\left.\mathrm{s}, H_{5,5}, \mathrm{Me}_{2} \mathrm{biim}\right)$, 3.55-3.31, 3.05-2.75, 2.59, 2.54 (s, $\mathrm{CH}_{3} \mathrm{SOCH}_{3}$ and $\mathrm{CH}_{3}-\mathrm{Me}_{2} \mathrm{biim}$ ), 2.65 ( s , free DMSO). IR ( KBr pellet): v 3457 ( $\mathrm{s}, \mathrm{N}-\mathrm{H}$ ), 1086(s, S=O), 1081 ( $\mathrm{s}, \mathrm{S}=\mathrm{O}$ ). ESI-MS (MeOH): 785 $\left(\mathrm{M}^{+}-\mathrm{Cl}\right), 707\left(\mathrm{M}^{+}-\mathrm{Cl}-\mathrm{DMSO}\right), 629\left(\mathrm{M}^{+}-\mathrm{Cl}-2 \mathrm{DMSO}\right), 551\left(\mathrm{M}^{+}-\mathrm{Cl}-3 \mathrm{DMSO}\right)$. $\Lambda_{M}(\mathrm{MeOH})=97 \Omega^{-1} \mathrm{~cm}^{2} \mathrm{~mol}^{-1}$. Anal. Calcd for $\mathrm{C}_{16} \mathrm{H}_{34} \mathrm{Cl}_{4} \mathrm{~N}_{4} \mathrm{O}_{4} \mathrm{~S}_{4} \mathrm{Ru}_{2}$ : C, 23.47; H, 4.16; N, 6.85. Found: C, 23.58; H, 4.19; N, 6.65.

### 4.9.5 $[\mathrm{Ru} \text { (maltolato) })_{2}($ biim $\left.)\right] \mathrm{CF}_{3} \mathrm{SO}_{3} \cdot \mathbf{2 \mathrm { H } _ { 2 } \mathrm { O }}$ (24)

To a solution of $\left[\mathrm{Ru}(\text { maltolato })_{2}(\mathrm{EtOH})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$ (3) $(0.088 \mathrm{~g}, 0.15 \mathrm{mmol})$ in 5 mL EtOH was added $\mathrm{H}_{2}$ biim ( $0.055 \mathrm{~g}, 0.15 \mathrm{mmol}$ ), and the mixture was refluxed under $\mathrm{N}_{2}$ for 24 h , when it slowly turned brown. After 24 h , the solvent was removed under vacuum and the brown residue was redissolved in acetone; this was cooled to $0{ }^{\circ} \mathrm{C}$ and then filtered through Celite $(2 \mathrm{~g})$. The filtrate was warmed to r.t. and reduced in volume
to 2 mL . Hexanes ( 15 mL ) were then added to yield a brown precipitate that was collected, washed with hexanes ( $2 \times 5 \mathrm{~mL}$ ) and dried at $78{ }^{\circ} \mathrm{C}$ under vacuum for 48 h . Yield $0.054 \mathrm{~g}(58 \%) .{ }^{1} \mathrm{H} \operatorname{NMR}\left(\mathrm{CDCl}_{3}\right): \delta 52.7$ (br s, $\mathrm{CH}_{3}$-ma), -7.0 (br s, $H_{5,5}$-biim), -
 1548 (m), 1467 (m), 1264 (m), 1031 ( s$)$. LR-MS (+LSIMS, thioglycerol): $486\left(\mathrm{M}^{+}\right), 361$ $\left(\mathrm{M}^{+}-\mathrm{ma}\right) . \quad \Lambda_{\mathrm{M}}(\mathrm{MeOH})=106 \Omega^{-1} \mathrm{~cm}^{2} \mathrm{~mol}^{-1} . \mathrm{CV}(\mathrm{MeCN}): \mathrm{E}_{1 / 2} \quad\left(\mathrm{Ru}^{\mathrm{IIIIII}}\right)=-0.101 \mathrm{~V}$. Anal. Calcd for $\mathrm{C}_{19} \mathrm{H}_{16} \mathrm{~F}_{3} \mathrm{~N}_{4} \mathrm{O}_{9} \mathrm{SRu} \cdot 2 \mathrm{H}_{2} \mathrm{O}: \mathrm{C}, 34.02 ; \mathrm{H}, 2.99 ; \mathrm{N}, 8.36$. Found: C, 34.11; H, 2.89; N, 8.18.

### 4.9.6 $\left.[\mathrm{Ru} \text { (maltolato) })_{2}\left(\mathrm{Me}_{2} \mathrm{biim}\right)\right] \mathrm{CF}_{3} \mathrm{SO}_{3} \cdot \mathbf{2} \mathbf{H}_{2} \mathrm{O}$ (25)

This complex was prepared using the same procedure of section 4.9 .5 but using $\mathbf{3}$ $(0.090 \mathrm{~g}, 0.15 \mathrm{mmol})$ and $\mathrm{H}_{2} \mathrm{Me}_{2}$ biim $(0.060 \mathrm{~g}, 0.15 \mathrm{mmol})$. Yield $0.061 \mathrm{~g}(61 \%) .{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta 64.8,60.6$ (br s, $\left.\mathrm{CH}_{3}-\mathrm{ma}\right), 42.1,37.5$ (br s, $\mathrm{CH}_{3}-\mathrm{Me}_{2} \mathrm{biim}$ ), -9.1 br (s, $H_{5,5}-\mathrm{Me}_{2} \mathrm{biim}$ ). IR ( KBr pellet): v 3550 (O-H, s), 2916 (C-H, m), 1602 (C=O, m), 1542 $(\mathrm{m}), 1468(\mathrm{~m}), 1263(\mathrm{~m}), 1030(\mathrm{~s})$. ESI-MS: $514\left(\mathrm{M}^{+}\right), 389\left(\mathrm{M}^{+}-\mathrm{ma}\right) . \Lambda_{\mathrm{M}}(\mathrm{MeOH})=$ $127 \Omega^{-1} \mathrm{~cm}^{2} \mathrm{~mol}^{-1}$. $\mathrm{CV}(\mathrm{MeCN}): \mathrm{E}_{1 / 2}\left(\mathrm{Ru}^{\mathrm{IIIIII}}\right)=-0.035 \mathrm{~V}$ vs. SCE. Anal. Calcd for $\mathrm{C}_{21} \mathrm{H}_{20} \mathrm{~F}_{3} \mathrm{~N}_{4} \mathrm{O}_{9} \mathrm{SRu} \cdot 2 \mathrm{H}_{2} \mathrm{O}: \mathrm{C}, 36.00 ; \mathrm{H}, 3.43$; N, 8.00. Found: C, $35.92 ; \mathrm{H}, 3.28 ; \mathrm{N}, 8.17$.

### 4.9.7 $\left[\mathrm{Ru}(\mathrm{biim})_{3}\right]\left[\mathrm{CF}_{3} \mathrm{SO}_{3}\right]_{2}$ (26)

To a solution of $\left[\mathrm{Ru}(\mathrm{DMF})_{6}\right]\left[\mathrm{CF}_{3} \mathrm{SO}_{3}\right]_{3}(0.083 \mathrm{~g}, 0.085 \mathrm{mmol})$ in $\mathrm{MeOH}(5 \mathrm{~mL})$ was added $\mathrm{H}_{2}$ biim ( $0.12 \mathrm{~g}, 0.34 \mathrm{mmol}$ ). This yellow solution was refluxed; after 10 h , the solution had turned green and after 24 h had become very dark green. The solvent was removed under vacuum and the green residue was redissolved in acetone ( 10 mL ); the mixture was filtered through Celite, and the filtrate was then reduced in volume to $\sim 1$ mL . To this was added hexanes ( 8 mL ) to yield a green precipitate that was collected, washed with hexanes ( $2 \times 5 \mathrm{~mL}$ ), and dried under vacuum at $78^{\circ} \mathrm{C}$ for 24 h . Yield: 0.034 g (60 \%). ${ }^{1} \mathrm{H}$ NMR ( $\mathrm{CD}_{3} \mathrm{OD}$ ): $\delta 8.37$ (s, $6 \mathrm{H}, H_{2,2^{\prime}}$-biim), 7.62 (s, $6 \mathrm{H}, H_{5,5}$-biim). ESIMS (MeOH): $652\left(\mathrm{M}^{+}-\mathrm{CF}_{3} \mathrm{SO}_{3}\right), 502\left(\mathrm{M}^{+}-2 \mathrm{CF}_{3} \mathrm{SO}_{3}\right), 369\left(\mathrm{M}^{+}-2 \mathrm{CF}_{3} \mathrm{SO}_{3}-\right.$ biim $) . \Lambda_{\mathrm{M}}$ $(\mathrm{MeOH})=243 \Omega^{-1} \mathrm{~cm}^{2} \mathrm{~mol}^{-1}$. Anal. Calcd for $\mathrm{C}_{20} \mathrm{H}_{18} \mathrm{~F}_{6} \mathrm{~N}_{12} \mathrm{O}_{6} \mathrm{~S}_{2} \mathrm{Ru}: \mathrm{C}, 29.96 ; \mathrm{H}, 2.25 ; \mathrm{N}$, 20.97. Found: C, 29.75; H, 2.31; N, 20.64.

### 4.9.8 $\left[\mathrm{Ru}\left(\mathrm{Me}_{2} \mathrm{biim}\right)_{3}\right]\left[\mathrm{CF}_{3} \mathrm{SO}_{3}\right]_{2}$

To a solution of $\left[\mathrm{Ru}(\mathrm{DMF})_{6}\right]\left[\mathrm{CF}_{3} \mathrm{SO}_{3}\right](0.074 \mathrm{~g}, 0.075 \mathrm{mmol})$ in $\mathrm{MeOH}(5 \mathrm{~mL})$ was added $\mathrm{H}_{2} \mathrm{Me}_{2}$ biim ( $0.12 \mathrm{~g}, 0.30 \mathrm{mmol}$ ). This yellow solution was refluxed for 16 h ; the solution turned brown after 2 h and slowly became dark blue in colour. After 16 h , the solvent was removed under vacuum and the black residue was redissolved in acetone (10 mL ); this mixture was filtered through Celite, and the filtrate reduced in volume to $\sim 1$ mL . To this was added hexanes ( 8 mL ) to yield a blue precipitate that was subsequently collected and dried under vacuum at $78{ }^{\circ} \mathrm{C}$ for 24 h . Yield: $0.042 \mathrm{~g}(63 \%) .{ }^{1} \mathrm{H}$ NMR ( $\mathrm{CD}_{3} \mathrm{OD}$ ): $\delta 7.43$ (s, $6 \mathrm{H}, H_{5,5}{ }^{\prime}-\mathrm{Me}_{2} \mathrm{biim}$ ), 2.54 ( $\mathrm{s}, 18 \mathrm{H}, \mathrm{CH}_{3}-\mathrm{Me}_{2} \mathrm{biim}$ ). ESI-MS (MeOH): $736\left(\mathrm{M}^{+}-\mathrm{CF}_{3} \mathrm{SO}_{3}\right), 587\left(\mathrm{M}^{+}-2 \mathrm{CF}_{3} \mathrm{SO}_{3}\right), 575\left(\mathrm{M}^{+}-\mathrm{CF}_{3} \mathrm{SO}_{3}-\mathrm{Me}_{2} \mathrm{biim}\right), 425\left(\mathrm{M}^{+}-2\right.$ $\mathrm{CF}_{3} \mathrm{SO}_{3}-\mathrm{Me}_{2}$ biim). Anal. Calcd for $\mathrm{C}_{26} \mathrm{H}_{30} \mathrm{~F}_{6} \mathrm{~N}_{12} \mathrm{O}_{6} \mathrm{~S}_{2} \mathrm{Ru}$ : C, 35.25; H, 3.39; N, 18.98 . Found: C, 35.16; H, 3.32; N, 18.44.

### 4.9.9 $\left[\mathrm{Ru}(\mathrm{Hbiim})_{2} \mathrm{Cl}_{2}\right] \mathrm{Cl}_{2}$ (28)

$\mathrm{H}_{2}$ was bubbled through a solution of $\mathrm{RuCl}_{3} \cdot 3 \mathrm{H}_{2} \mathrm{O}(0: 054 \mathrm{~g}, 0.21 \mathrm{mmol})$ in refluxing MeOH for 3 h at which time the brown solution had become blue. To this solution was added $\mathrm{H}_{2}$ biim ( $0.15 \mathrm{~g}, 0.40 \mathrm{mmol}$ ). and the mixture was refluxed for 10 h under $1 \mathrm{~atm} \mathrm{H}_{2}$ when it slowly turned brown. The solvent was then reduced in volume under vacuum to $\sim 1 \mathrm{~mL}$ and acetone ( 5 mL ) was added to yield a brown precipitate that was collected, washed with acetone ( $2 \times 5 \mathrm{~mL}$ ), and dried under vacuum at $78^{\circ} \mathrm{C}$ for 24 h. Yield: $0.042 \mathrm{~g}(42 \%) .{ }^{\mathrm{l}} \mathrm{H} \operatorname{NMR}\left(\mathrm{D}_{2} \mathrm{O}\right): \delta 8.59$ (br s, $H_{2,2^{\prime}}$-biim), 7.58 (br s, $H_{5,5^{\prime}}$ biim). ESI-MS $\left(\mathrm{H}_{2} \mathrm{O}\right): 440\left(\mathrm{M}^{+}-2 \mathrm{H}\right), 404\left(\mathrm{M}^{+}-\mathrm{H}-\mathrm{Cl}\right) . \Lambda_{\mathrm{M}}\left(\mathrm{H}_{2} \mathrm{O}\right)=265 \Omega^{-1} \mathrm{~cm}^{2} \mathrm{~mol}^{-1}$. Anal. Calcd for $\mathrm{C}_{12} \mathrm{H}_{14} \mathrm{Cl}_{4} \mathrm{~N}_{8} \mathrm{Ru}$ : C, 28.07; H, 2.73; N, 21.83. Found: C, 27.92; H, 2.79; N, 21.59.

### 4.9.10 $\left[\mathrm{Ru}\left(\mathrm{HMe}_{2} \mathrm{biim}\right)\left(\mathrm{Me}_{2} \mathrm{biim}\right)_{2}\right] \mathrm{Cl}_{3}$ (29)

The procedure of Section 4.9 .9 was followed but using $\mathrm{RuCl}_{3} \cdot 3 \mathrm{H}_{2} \mathrm{O}(0.042 \mathrm{~g}, 0.16$ mmol ) and $\mathrm{H}_{2} \mathrm{Me}_{2}$ biim ( $0.13 \mathrm{~g}, 0.33 \mathrm{mmol}$ ); also $\mathrm{Et}_{2} \mathrm{O}(5 \mathrm{~mL})$ rather than acetone was added to give the brown product. Yield: $0.034 \mathrm{~g}(30 \%) .{ }^{1} \mathrm{H} \operatorname{NMR}\left(\mathrm{D}_{2} \mathrm{O}\right): \delta 7.71$ (br s, $1 \mathrm{H}, H_{5,5}-\mathrm{Me}_{2} \mathrm{biim}$ ), 1.68 (br s, $3 \mathrm{H}, \mathrm{CH}_{3}-\mathrm{Me}_{2}$ biim). ESI-MS $\left(\mathrm{H}_{2} \mathrm{O}\right): 587\left(\mathrm{M}^{+}-\mathrm{H}\right), 425$
( $\mathrm{M}^{+}-\mathrm{HMe}_{2}$ biim). $\quad \Lambda_{\mathrm{M}}\left(\mathrm{H}_{2} \mathrm{O}\right)=385 \Omega^{-1} \mathrm{~cm}^{2} \mathrm{~mol}^{-1}$. Anal. Calcd for $\mathrm{C}_{24} \mathrm{H}_{31} \mathrm{Cl}_{3} \mathrm{~N}_{12} \mathrm{Ru}: \mathrm{C}$, 41.47; H, 4.46; N, 24.19. Found: C, 41.25; H, 4.51; N, 23.93.

## Chapter 5

## Synthesis and Characterization of Ru Complexes with Chelating N-Heterocyclic Carboxylates

### 5.1 Introduction

The coordination of carboxylate groups to transition metals is typically investigated using $\mathbb{R}$ spectroscopy, the difference in the symmetric and asymmetric stretching frequencies being used to determine the coordination mode when X-ray structural data are not available (Figure 5.1). ${ }^{1,2}$

a

b

C

Figure 5.1 Binding modes of carboxylate groups with transition metal complexes; a) Monodentate, b) Chelating, and c) Bridging.

The coordination chemistry of pyridine-2-carboxylic acid, more commonly referred to as picolinic acid (Hpic) (Figure 5.2), has been widely studied. ${ }^{3-9}$ Hpic is a tryptophan metabolite, and its transition metal complexes may have biological implications. ${ }^{10}$ For example, $\mathrm{Cr}(\text { pic })_{3}$ is currently marketed as a nutritional supplement and weight-loss agent. ${ }^{8,11}$ Trace Cr is essential in the body, while $\mathrm{Cr}(\mathrm{pic})_{3}$ is readily absorbed by the body and shows a lack of toxicity at doses as high as 30 mg Cr per kg body weight in rats. ${ }^{12}$ The fate of the complex and nature of the absorbed active species, however, remain unknown. ${ }^{8}$ At a concentration of $120 \mu \mathrm{M}, \mathrm{Cr}(\mathrm{pic})_{3}$ on reduction can react with $\mathrm{O}_{2}$ to form hydroxyl radicals that possibly cleave DNA. ${ }^{11}$ At $\mathrm{pH}<1$, aqueous
solutions of $\mathrm{Cr}(\mathrm{pic})_{3}$ form $\left[\mathrm{Cr}(\text { pic })_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)\right]^{+}$, which may be the active species absorbed by the body. ${ }^{8}$

Figure 5.2 Molecular structure of pyridine-2-carboxylic acid, Hpic.

Ru readily forms bridged-carboxylate bimetallic complexes when reacted with carboxylic acids, ${ }^{13}$ for example, the $\mathrm{Ru}(I I / I I)$ bimetallic precursor used in the work discussed in this chapter, $\left[\mathrm{Ru}_{2}\left(\mu-\mathrm{CH}_{3} \mathrm{COO}\right)_{4} \mathrm{Cl}\right]$. Related oxo-centered Ru trimetallic carboxylate complexes have also been reported. ${ }^{13,14}$ More recently there have been reports of N -heterocyclic carboxylates chelating via N - and O -atoms to Ru to form monomeric complexes. For example, mer- $\mathrm{Ru}(\mathrm{pic})_{3} \cdot \mathrm{H}_{2} \mathrm{O}$ has been synthesized from $\mathrm{K}_{2}\left[\mathrm{RuCl}_{5}\left(\mathrm{H}_{2} \mathrm{O}\right)\right],{ }^{3}\left[\mathrm{Ru}_{2}\left(\mu-\mathrm{CH}_{3} \mathrm{COO}\right)_{4} \mathrm{Cl}\right],{ }^{4}$ and $\mathrm{RuCl}_{3} \cdot 3 \mathrm{H}_{2} \mathrm{O} ;{ }^{5}$ however, this complex is only sparingly soluble in aqueous solution thus limiting its potential for biological applications. In Section 5.2, a new $\mathrm{Ru}(\mathrm{II} / \mathrm{I})$ bimetallic picolinate complex is described; this complex is highly water-soluble, and may have useful biological applications. Reactions analogous to those reported in the literature with Ru and Hpic, but using instead imidazole-4-carboxylic acid $\left(\operatorname{Im}-\mathrm{CO}_{2} \mathrm{H}\right)$, will then be discussed in Section 5.3. Finally, some preliminary work with a third ligand, 3-nitro-1,2,4-triazole-5-carboxylic acid (HCANT), will be presented. In Section 3.3.3, it was noted that Ru-maltolato complexes containing $2 \mathrm{NO}_{2} \mathrm{Im}, 4 \mathrm{NO}_{2} \mathrm{Im}$ or $3 \mathrm{NO}_{2}$ tri ligands were not stable in DMSO solution and were insoluble in other solvents. It was thought, therefore, that as two of the carboxylate complexes discussed in this chapter $\left(\left[\mathrm{Ru}_{2}(\mathrm{pic})_{4}(\mathrm{EtOH}) \mathrm{Cl}\right] \cdot \mathrm{H}_{2} \mathrm{O}\right.$ (31) and $\left.\mathrm{Ru}\left(\mathrm{Im}-\mathrm{CO}_{2}\right)\left(\mathrm{Im}-\mathrm{CO}_{2} \mathrm{H}\right)_{2} \mathrm{Cl}_{2} \cdot \mathrm{EtOH} \cdot \mathrm{H}_{2} \mathrm{O}(\mathbf{3 3})\right)$ exhibited high water-solubility, that Ru complexes with HCANT might also be water-soluble and thus have potential for further biological testing.

### 5.2 Synthesis and Characterization of $\left[\mathrm{Ru}_{2}(\mathrm{pic})_{4}(\mathrm{EtOH}) \mathrm{Cl}\right] \cdot \mathrm{H}_{2} \mathrm{O}(31)$

mer- $\mathrm{Ru}(\text { pic })_{3} \cdot \mathrm{H}_{2} \mathrm{O}(\mathbf{3 0})$ is a yellow solid, sparingly soluble in water and DMSO, and completely insoluble in other solvents tested. ${ }^{4}$ The synthesis of $\mathbf{3 0}$ was carried out using a modification of procedures reported by Ellis et al. ${ }^{3}$ and Barral et al. ${ }^{4}$ Both groups used base to deprotonate Hpic in solution; however, base was found to be unnecessary and yields obtained were similar to those reported. The reaction of Hpic with $\mathrm{RuCl}_{3} \cdot 3 \mathrm{H}_{2} \mathrm{O}$, reported by Ghatak et al., ${ }^{5}$ was also repeated. Again, the procedure was modified to omit base; however, this time $\mathbf{3 0}$ was not formed, and an orange solid (31) was isolated. The $\mathrm{RuCl}_{3} \cdot 3 \mathrm{H}_{2} \mathrm{O}$ reaction was also repeated with base as reported, ${ }^{5}$ but neither $\mathbf{3 0}$ nor any other identifiable species could be isolated. A precipitated black solid had very low $\mathrm{C}(6.2 \%)$ and $\mathrm{N}(1.4 \%)$ content and thus contained minimal picolinate.

Elemental analysis of 31 supports the formulation $\left[\mathrm{Ru}_{2}(\mathrm{pic})_{4}(\mathrm{EtOH}) \mathrm{Cl}\right] \cdot \mathrm{H}_{2} \mathrm{O}$. The MS data (in MeOH ), showing a Ru dinuclear splitting pattern with a parent peak for [ $\left.\mathrm{M}^{+}-\mathrm{EtOH}\right]$ at 727 (Figure 5.3), also support this formulation. This pattern is easily identified compared to that of a mononuclear species because of the distinct isotopic splitting for a $\mathrm{Ru}_{2}$ species vs. that for one Ru atom (Figure 5.4).

Figure 5.3 ESI-MS spectrum (in MeOH) of $\left[\mathrm{Ru}_{2}(\text { pic })_{4}(\mathrm{EtOH}) \mathrm{Cl}\right] \cdot \mathrm{H}_{2} \mathrm{O}$ (31) clearly showing the $\left[\mathrm{M}^{+}-\mathrm{EtOH}\right]$ fragment centered at 727.

Figure 5.4 Theoretical isotopic distribution for the $\left[\mathrm{M}^{+}\right]$peak of $\mathrm{Ru}\left(\mathrm{Im}-\mathrm{CO}_{2}\right)$ ( Im $\left.\mathrm{CO}_{2} \mathrm{H}\right)_{2} \mathrm{Cl}_{2} \cdot \mathrm{EtOH} \cdot \mathrm{H}_{2} \mathrm{O}$ (33, left) (Section 5.3), and for the [ $\left.\mathrm{M}^{+}-\mathrm{EtOH}\right]$ peak of $\left[\mathrm{Ru}_{2}(\text { pic })_{4}(\mathrm{EtOH}) \mathrm{Cl}\right] \cdot \mathrm{H}_{2} \mathrm{O}$ (31, right), clearly showing the difference in isotopic splitting patterns between a Ru and a $\mathrm{Ru}_{2}$ species.

The IR data for 31 (Table 5.1) show that the carboxylate groups are not bridging, and that the bridging is likely via one O -atom and the pyridine-N. For bridging carboxylate groups, the difference between $v_{\text {sym }}$ and $v_{\text {asym }}$ is typically $<150 \mathrm{~cm}^{-1}$ for $\mathrm{Ru}_{2}$ complexes; ${ }^{1}$ for $\mathbf{3 1} \Delta v$ is $\sim 300 \mathrm{~cm}^{-1}$, suggesting that the carboxylate group is binding in a monodentate fashion, similar to that observed for $\mathbf{3 0}$.

Table 5.1 Selected IR spectral data for Ru carboxylate complexes.

| Complex | $v_{\text {asym }}$ <br> $\left(\mathrm{cm}^{-1}\right)$ | $v_{\text {sym }}$ <br> $\left(\mathrm{cm}^{-1}\right)$ |
| :--- | :---: | :---: |
| $m e r-\mathrm{Ru}(\text { pic })_{3} \cdot \mathrm{H}_{2} \mathrm{O}(\mathbf{3 0})$ | 1661 | 1315 |
| $\left[\mathrm{Ru}(\mathrm{pic})_{4}(\mathrm{EtOH}) \mathrm{Cl}\right] \cdot \mathrm{H}_{2} \mathrm{O}(\mathbf{3 1 )}$ | 1672,1639 | 1396,1316 |
| $\mathrm{Ru}\left(\mathrm{Im}-\mathrm{CO}_{2}\right)_{3} \cdot 2 \mathrm{H}_{2} \mathrm{O}(\mathbf{3 2 )}$ | 1642 | 1324 |
| $\mathrm{Ru}\left(\mathrm{Im}-\mathrm{CO}_{2}\right)\left(\mathrm{Im}-\mathrm{CO}_{2} \mathrm{H}\right)_{2} \mathrm{Cl}_{2} \cdot \mathrm{EtOH} \cdot \mathrm{H}_{2} \mathrm{O}(\mathbf{3 3})$ | $1718,1706,1570$ | $1384,1350,1313$ |

The strong IR band at $3468 \mathrm{~cm}^{-1}$ is assigned to $v_{\mathrm{OH}}$ and could be for either coordinated EtOH or the $\mathrm{H}_{2} \mathrm{O}$ solvate. The bound EtOH is more easily identified by the ${ }^{1} \mathrm{H}$ NMR data (Figure 5.5): two broadened resonances (the Me-triplet at $\delta 1.45$, and the $\mathrm{CH}_{2}$ quartet at $\delta 4.53$ ) are shifted downfield from those of free EtOH (with the Me-triplet at $\delta 1.12$, and the $\mathrm{CH}_{2}$ quartet at $\delta 3.55$ ). The relative intensities of the free and bound EtOH resonances in $\mathrm{D}_{2} \mathrm{O}$ imply that in this solvent, $\sim 40 \%$ of $\mathbf{3 1}$ is converted to a species with coordinated $\mathrm{D}_{2} \mathrm{O}$.

Figure 5.5 ${ }^{\mathrm{I}} \mathrm{H}$ NMR spectrum ( $300 \mathrm{MHz}, 298 \mathrm{~K}$ ) of $\left[\mathrm{Ru}_{2}(\mathrm{pic})_{4}(\mathrm{EtOH}) \mathrm{Cl}^{2} \cdot \mathrm{H}_{2} \mathrm{O}(\mathbf{3 1})\right.$ in $\mathrm{D}_{2} \mathrm{O}$. a) Complete spectrum. b) Expansion showing signals of the bound EtOH at $\delta 4.53$ and 1.45 highlighted with boxes.

Barral et al. ${ }^{4}$ have reported the synthesis of $\left[\mathrm{Ru}_{2}(\mathrm{pic})_{4}\right]$, with a proposed structure containing either four bridging N,O-pic ligands or two bridging N,O-pic ligands and two
non-bridging $\eta^{2}$-pic ligands. Similar structures with four bridging pic ligands, each Ru having a terminal EtOH or Cl (Figure 5.6a), or two $\mu$-pic ligands and two, non-bridging $\eta^{2}$-pic ligands, one on each Ru (Figure 5.6b), are plausible for 31. The conductivity for 31 in MeOH is $112 \Omega^{-1} \mathrm{~cm}^{2} \mathrm{~mol}^{-1}$, in the range for a $1: 1$ electrolyte, ${ }^{15,16}$ suggesting $\mathrm{Cl}^{-}$ dissociation. If the $\mathrm{Cl}^{-}$was bridging, its dissociation in solution would likely lead to decomposition of the bimetallic unit; however, ESI-MS data in MeOH show it to be still intact.
a)

b)

Figure 5.6 Proposed solid state structures for $\mathbf{3 1}$ where $\mathrm{N}-\mathrm{O} \equiv$ pic. a) unit with four bridging pic ligands. b) unit with two bridging and two non-bridging pic* ligands.

### 5.3 Complexes of Ru with Imidazole-4-carboxylic Acid

### 5.3.1 Synthesis and Characterization of $\mathbf{R u}\left(\mathrm{Im}-\mathrm{CO}_{2}\right)_{3} \cdot \mathbf{2 \mathrm { H } _ { 2 } \mathrm { O }}$ (32)

In reactions similar to those reported for the synthesis of $\mathrm{Ru}(\mathrm{pic})_{3} \cdot \mathrm{H}_{2} \mathrm{O}$ (30) (Section 5.2), $\mathrm{Ru}\left(\operatorname{Im}-\mathrm{CO}_{2}\right)_{3}$ was synthesized from both $\mathrm{K}_{3} \mathrm{RuCl}_{6}$ and $\mathrm{Ru}_{2}$ (acetate) $)_{4} \mathrm{Cl}$, using $\mathrm{Im}-\mathrm{CO}_{2} \mathrm{H}$ (Figure 5.7) in place of Hpic. ${ }^{3,4}$ The isolated, pale yellow product, was characterized by elemental analysis, MS, and IR and NMR spectroscopies. Elemental analysis was consistent with the formulation of $\mathrm{Ru}\left(\operatorname{Im}-\mathrm{CO}_{2}\right)_{3} \cdot 2 \mathrm{H}_{2} \mathrm{O}$. The $\Delta v$ value of 318 $\mathrm{cm}^{-1}$ for $\nu_{\text {asym }}-v_{\text {sym }}$ (Table 5.1) is consistent with a chelated structure with binding via the imidazole- $\mathrm{N}(3)$ and one carboxylate- O atom as for $\mathrm{Ru}(\mathrm{pic})_{3} \cdot \mathrm{H}_{2} \mathrm{O}$; the presence of water is indicated by a $\nu_{\mathrm{OH}}$ at $3423 \mathrm{~cm}^{-1}$, and by an increase in intensity of the residual
water signal in dmso- $d_{6}$ in the spectrum of the complex compared with that of a blank of the solvent containing no complex.

Figure 5.7 Molecular structure of $\mathrm{Im}-\mathrm{CO}_{2} \mathrm{H}$.

32 is only sparingly soluble in DMSO, and is insoluble in other solvents. The ${ }^{1} \mathrm{H}$ NMR spectrum in dmso- $d_{6}$ (recorded over $6 \mathrm{~h}, \sim 20,000$ scans) shows 6 very weak resonances for the bound imidazoles at $\delta 0.31,0.09$ and -0.09 for $\mathrm{H}(5)$ and $\delta-2.67$, 13.55 and -17.87 for $\mathrm{H}(2)$, the assignments being based on those observed for monodentate imidazole ligands with $\mathrm{Ru}(Ш \mathrm{~W})$ (Section 3.3.2).

As for the synthesis of $\mathrm{Ru}(\mathrm{pic})_{3} \cdot \mathrm{H}_{2} \mathrm{O}(\mathbf{3 0})$, no base was used in the synthesis of $\mathbf{3 2}$. With the use of 3 equivalents of base to reproduce the reaction conditions reported for the synthesis of $\mathbf{3 0},{ }^{3-5} \mathbf{3 2}$ was not formed; the isolated products using $\operatorname{Im}-\mathrm{CO}_{2} \mathrm{H}$ under basic conditions were not identified but contained very low percentages of C and N , both below $10 \%$, as was found when $\mathrm{RuCl}_{3} \cdot 3 \mathrm{H}_{2} \mathrm{O}$ was reacted under basic conditions with Hpic (Section 5.2).

### 5.3.2 Synthesis and Characterization of $\mathrm{Ru}\left(\mathrm{Im}-\mathrm{CO}_{2}\right)\left(\mathrm{Im}-\mathrm{CO}_{2} \mathrm{H}\right)_{2} \mathrm{Cl}_{2} \cdot \mathrm{EtOH} \cdot \mathrm{H}_{2} \mathrm{O}$ (33)

There are currently no literature examples of Ru complexes containing $\mathrm{Im}-\mathrm{CO}_{2} \mathrm{H}$ (Figure 5.7) or $\mathrm{Im}-\mathrm{CO}_{2}{ }^{-}$as a ligand. The only such transition metal complexes reported are a pair of Mn clusters in which $\mathrm{Im}-\mathrm{CO}_{2}{ }^{-}$chelates through a carboxylate-O and the imidazole- $\mathrm{N}(3) .{ }^{17}$ There is, however, one reported Ru complex with imidazole 4,5dicarboxylic acid, ${ }^{18}$ where $\mathbb{R}$ stretches for both bound $-\mathrm{COO}^{-}$and free -COOH are reported; these have proved useful in the formulation of $\mathrm{Ru}\left(\mathrm{Im}-\mathrm{CO}_{2}\right)(\mathrm{Im}$ $\left.\mathrm{CO}_{2} \mathrm{H}\right)_{2} \mathrm{Cl}_{2} \cdot \mathrm{EtOH} \cdot \mathrm{H}_{2} \mathrm{O}(\mathbf{3 3})$.

Unlike the reaction of $\mathrm{RuCl}_{3} \cdot 3 \mathrm{H}_{2} \mathrm{O}$ with Hpic , the reaction with $\mathrm{Im}-\mathrm{CO}_{2} \mathrm{H}$ does not form a bimetallic complex. 33 is synthesized by refluxing $\mathrm{Im}-\mathrm{CO}_{2} \mathrm{H}$ and $\mathrm{RuCl}_{3} \cdot 3 \mathrm{H}_{2} \mathrm{O}$ in a $3: 1$ ratio in EtOH (Figure 5.8). The IR data show two distinct types of carboxylates with $v_{\text {asym }}=1718,1706$, and 1570 (Table 5.1). For $\left[\mathrm{Ru}\left(\mathrm{PPh}_{3}\right)_{2}(\mathrm{~L}-\mathrm{H})_{2}\right]\left(\mathrm{L}-\mathrm{H}_{2}=\right.$ imidazole 4,5-dicarboxylic acid) (Figure 5.9), $v_{\text {asym }}$ for the protonated carboxylic acid group was observed at $1720 \mathrm{~cm}^{-1}$ and for the bound carboxylate was observed at 1627 $\mathrm{cm}^{-1} .{ }^{18}$ This suggests that for 33 , the stretches at 1718 and $1706 \mathrm{~cm}^{-1}$ are for -COOH groups, and the stretch at $1577 \mathrm{~cm}^{-1}$ is for a bound $-\mathrm{COO}^{-}$.

Figure 5.8 One possible isomer for the proposed structure for $\mathrm{Ru}\left(\mathrm{Im}-\mathrm{CO}_{2}\right)(\mathrm{Im}$ $\mathrm{CO}_{2} \mathrm{H}_{2} \mathrm{Cl}_{2} \cdot \mathrm{EtOH} \cdot \mathrm{H}_{2} \mathrm{O}(\mathbf{3 3})$ (solvent molecules not shown).

Figure 5.9 Molecular structure of $\left[\mathrm{Ru}\left(\mathrm{PPh}_{3}\right)_{2}(\mathrm{~L}-\mathrm{H})_{2}\right]\left(\mathrm{L}-\mathrm{H}_{2}=\right.$ imidazole 4,5dicarboxylic acid). ${ }^{18}$

ESI-MS data (in MeOH ) show a parent peak for 33 at 508 (Figure 5.10) with the same isotopic splitting pattern as that of a theoretically calculated spectrum (see Figure 5.4). In MeOH , the conductivity of 33 over 3 h remained at $19-23 \Omega^{-1} \mathrm{~cm}^{2} \mathrm{~mol}^{-1}$, consistent with a neutral species. ${ }^{15,16}$

Figure 5.10 Mass spectrum of $\mathrm{Ru}\left(\operatorname{Im}-\mathrm{CO}_{2}\right)\left(\operatorname{Im}-\mathrm{CO}_{2} \mathrm{H}\right)_{2} \mathrm{Cl}_{2} \cdot \mathrm{EtOH} \cdot \mathrm{H}_{2} \mathrm{O}$, showing $\mathrm{M}^{+}$at 508.

A more exact structural formulation for $\mathbf{3 3}$ cannot be given, but the elemental analysis requires EtOH and $\mathrm{H}_{2} \mathrm{O}$ solvates. From the ${ }^{1} \mathrm{H}$ NMR spectrum in $\mathrm{CD}_{3} \mathrm{OD}$, both Im $-\mathrm{CO}_{2} \mathrm{H}$ ligands are likely in different chemical environments as three signals are observed for both the $\mathrm{H}(2)$ and $\mathrm{H}(5)$ protons of the $\mathrm{Im}-\mathrm{CO}_{2} \mathrm{H}$ and $\mathrm{Im}-\mathrm{CO}_{2}$ ligands. Resonances for free EtOH are also observed in the ${ }^{1} \mathrm{H}$ NMR spectrum, while a strong IR band at $3467 \mathrm{~cm}^{-1}$ may show evidence for the water solvate.

### 5.4 Synthesis of Nitroimidazole and Nitrotriazole Carboxylic Acids

### 5.4.1 Synthesis of 3-Nitro-1,2,4-triazole-5-carboxylic Acid (HCANT)

The synthetic procedure for HCANT was modified from a general procedure published by Pevzner and coworkers for nitrating numerous aminotriazole compounds. ${ }^{19,20}$ The precursor, 3-amino-1,2,4-triazole-5-carboxylic acid, was first synthesized using a reported procedure, ${ }^{21}$ but was later purchased from Aldrich when it became available commercially in 2002. The nitration procedure used is an example of a Sandmeyer reaction. ${ }^{22}$ The literature reports that the amino precursor is soluble in acetic acid; however this was found to be incorrect. In order to solubilize the amine-triazole, a higher $\mathrm{H}_{2} \mathrm{SO}_{4}: \mathrm{CH}_{3} \mathrm{COOH}$ ratio was used for formation of the diazonium salt. The amino group is first converted to a diazonium salt, followed by the facile replacement of the $-\mathrm{N}^{+} \equiv \mathrm{N}$ group by $\mathrm{NO}_{2}{ }^{-}$. Caution must be taken in adding the diazonium salt solution to the $\mathrm{NaNO}_{2}$ solution as rapid addition can lead to a violent reaction, producing a foam that erupts from the flask; dropwise addition with rapid stirring and gentle heating prevents this. The isolated solid was characterized by elemental analysis, mass spectrometry and IR spectroscopy.

Figure 5.11 Molecular structure of HCANT.

### 5.4.2 Attempted Synthesis of 2-Nitroimidazole-4-carboxylic Acid

4-Hydroxymethyl-2-nitroimidazole was synthesized using a modified literature procedure to afford initially 4-hydroxymethyl-1-tritylimidazole, the imidazole precursor for the nitration step. ${ }^{23}$ Davis and coworkers report the synthesis of this compound in 4 steps from imidazole-4,5-dicarboxylic acid. The first step, the synthesis of $\operatorname{Im}-\mathrm{CO}_{2} \mathrm{H}$,
was omitted as this material was purchased (Aldrich). Then the methyl ester, rather than the reported ethyl ester, was synthesized and characterized by ${ }^{1} \mathrm{H}$ NMR and $\mathbb{R}$ spectroscopies and mass spectrometry. As for the synthesis of $\mathrm{H}_{2}$ biim and $\mathrm{H}_{2} \mathrm{Me}_{2}$ biim (Chapter 4), the trityl group was used to protect the imidazole- $\mathrm{N}(1)$ position, as this group is easily removed with dilute acid once the nitration at the $\mathrm{C}(2)$ position is complete.

The reported procedure for reducing the ester group used $\mathrm{LiAlH}_{4},{ }^{23}$ but attempts to repeat this were unsuccessful. The $\mathrm{LiAlH}_{4}$ decomposed rapidly during workup upon the addition of water, indicating that it was still active. Diisobutylaluminum hydride (Dibal-H), using two equivalents per ester, was subsequently used successfully for reduction of the ester group at r.t over 1 h , although the isolated yield of 4 -hydroxymethyl-1-tritylimidazole was only $44 \%$ compared to the reported yield, $86 \%$, using $\mathrm{LiAlH}_{4}{ }^{23}$ This compound was also synthesized directly by treatment of 4(hydroxymethyl)imidazole with trityl chloride. The availability and cost of 4(hydroxymethyl)imidazole vary, but the relatively low yield from the ester reduction makes this second route economically viable.

The reported yield of 4-hydroxymethyl-2-nitroimidazole from 4-hydroxymethyl-1-tritylimidazole and $n$-propyl nitrate is $29 \% ;{ }^{23}$ however, two attempts to reproduce this reaction yielded only $\sim 3 \%$ of the desired product. When the same nitration procedure was used to synthesize 2 -nitroimidazole from 1-tritylimidazole, the yield of 2nitroimidazole obtained was $39 \%$, while the reported yield was $35-50 \%{ }^{23}$ This implies that there is no problem with the $n-\mathrm{BuLi}$ or $n$-propyl nitrate being used, or with the chromatographic set-up. The low yield of 4-hydroxymethyl-2-nitroimidazole prevented any attempt to oxidize it to 2-nitroimidazole-4-carboxylic acid. Either more work on optimizing the synthesis of 4-hydroxymethyl-2-nitroimidazole or a new synthetic route all together is needed in order to synthesize 2-nitroimidazole-4-carboxylic acid.

### 5.4.3 Attempted Synthesis of 2-Nitroimidazole-4,5-dicarboxylic Acid

As there is only one available position for substitution on the imidazole ring in imidazole-4,5-dicarboxylic acid, $\mathrm{C}(2)$, it was thought that introduction of a nitro group at this position might be facilitated by direct nitration using $\mathrm{HNO}_{3}$ or a mixture of $\mathrm{HNO}_{3}$ and $\mathrm{H}_{2} \mathrm{SO}_{4}$. Such a nitration might hopefully proceed in much higher yield than that
discussed for 4-hydroxymethyl-2-nitroimidazole in Section 5.4.2. The nitration of 4nitroimidazole to form 2,4-dintroimidazole has been reported, ${ }^{24}$ suggesting that nitration at this position is possible under certain conditions. Unfortunately, both imidazole-4,5dicarboxylic acid and dimethyl imidazole-4,5-dicarboxylate did not react with $\mathrm{HNO}_{3}$. After imidazole-4,5-dicarboxylic acid or the dimethyl ester was mixed with conc. $\mathrm{HNO}_{3}$ for 12 h , and the mixtures neutralized with 5 M NaOH , only the unreacted imidazoles were collected by filtration.

The reported procedure using $n$-propyl nitrate ${ }^{23}$ was then attempted with 4,5-bis(hydroxymethyl)-1-tritylimidazole; however, no nitrated species were observed and no products could be isolated from the reaction.

### 5.5 Attempted Reactions of HCANT with Ru Precursors

Reactions analogous to those discussed in Sections 5.2 and 5.3 with Hpic and Im$\mathrm{CO}_{2} \mathrm{H}$ were repeated using HCANT (Section 5.4.1) as a ligand. The reaction of three equivalents of HCANT with $\mathrm{K}_{3}\left[\mathrm{RuCl}_{6}\right]$ in $\mathrm{H}_{2} \mathrm{O}$ gave a purple solution from which a purple solid was isolated. The MS showed a parent peak consistent with the formulation of $\mathrm{Ru}(\mathrm{CANT})(\mathrm{HCANT})_{2} \mathrm{Cl}_{2}$, analogous to that of $\mathbf{3 3}$ synthesized from $\mathrm{RuCl}_{3} \cdot 3 \mathrm{H}_{2} \mathrm{O}$ (Section 5.3.2). In the IR spectrum, asymmetric $\mathrm{C}=\mathrm{O}$ stretches were observed at 1677 , 1665, and $1652 \mathrm{~cm}^{-1}$, and there was also a nitro stretch at $1542 \mathrm{~cm}^{-1}$. 25 An intense band at $1912 \mathrm{~cm}^{-1}$, however, suggests that either a coordinated $\mathrm{C} \equiv \mathrm{O}$ or $\mathrm{N} \equiv \mathrm{O}$ may be formed during the reaction. Elemental analysis (Anal. Calcd for $\mathrm{C}_{9} \mathrm{H}_{5} \mathrm{~N}_{12} \mathrm{O}_{12} \mathrm{Cl}_{2} \mathrm{Ru}: \mathrm{C}, 16.74 ; \mathrm{H}$, $0.78 ; \mathrm{N}, 26.05$. Found: C, $11.49 ; \mathrm{H}, 3.04 ; \mathrm{N}, 21.62$ ) of this purple solid was low in both C and N but high in H for the proposed formulation, possibly suggesting the presence of considerable water; consistent with the presence of a broad, intense band at $\sim 3400 \mathrm{~cm}^{-1}$ in the R spectrum.

The reaction of HCANT with $\mathrm{Ru}_{2}(\text { acetate })_{4} \mathrm{Cl}$ also gave a purple solution from which a purple solid was precipitated; its IR spectrum was the same as that mentioned above, except that the $1912 \mathrm{~cm}^{-1}$ band was now even more intense. ESI-MS (negative, MeOH ) showed only one peak at 444 with a clear Ru splitting pattern, consistent with the formulation of $\mathrm{Ru}(\mathrm{CANT})_{2}(\mathrm{NO})$; the stretch at $1912 \mathrm{~cm}^{-1}$ is in the range for $\mathrm{N} \equiv \mathrm{O}$ bound to $\mathrm{Ru}(\mathrm{III}) .{ }^{26-28}$ The elemental analysis (Anal. Calcd for $\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{~N}_{9} \mathrm{O}_{9} \mathrm{Ru}: \mathrm{C}, 16.18 ; \mathrm{H}, 0.45$;
$\mathrm{N}, 28.31$. Found: $\mathrm{C}, 15.34 ; \mathrm{H}, 2.56 ; \mathrm{N}, 24.35$ ) was also high in H and low in C and N for this proposed formulation.

Both reactions with HCANT gave products with reproducible $\mathbb{R}$ spectra that differ only in the intensity of the $1912 \mathrm{~cm}^{-1}$ band. The elemental analyses for the isolated purple solids, however, were not reproducible, but were always low in C and N and high in H . Further study on these complexes is needed to determine their nature.

### 5.6 Experimental Procedures

### 5.6.1 3-Nitro-1,2,4-triazole-5-carboxylic Acid (HCANT)

This compound was synthesized by a modified literature procedure. ${ }^{19,20}$ Sodium nitrite ( $1.10 \mathrm{~g}, 15.9 \mathrm{mmol}$ ) was added to 7 mL of $\mathrm{H}_{2} \mathrm{SO}_{4}$ at $-5^{\circ} \mathrm{C}$, and to this was added glacial acetic acid ( 15 mL ) and finely ground 3-amino-1,2,4-triazole-5-carboxylic acid $(2.00 \mathrm{~g}, 15.6 \mathrm{mmol})$. The mixture was stirred at $-5^{\circ} \mathrm{C}$ for 10 min until most of the triazole had dissolved; $\mathrm{H}_{2} \mathrm{O}(25 \mathrm{~mL})$ was then added with the temperature kept below 0 ${ }^{\circ} \mathrm{C}$. The resulting yellow solution was then added dropwise to a sodium nitrite solution ( $200 \mathrm{~g} \mathrm{NaNO}_{2}$ in $200 \mathrm{~mL} \mathrm{H}_{2} \mathrm{O}$ ) at $50^{\circ} \mathrm{C}$. (If added too quickly, a foam of diazonium salts can form, causing the reaction to heat up out of control with contents erupting from the flask.) The green product solution was heated for 2 h at $50^{\circ} \mathrm{C}$, when the now colourless solution was extracted with EtOAc ( $4 \times 50 \mathrm{~mL}$ ), and the combined extracts were evaporated yielding the desired product. Yield: 1.41 g ( $57 \%$ ). IR ( KBr pellet): $v$ 3416 (N-H, s), 3257 (O-H, m), 1710 (C=O, s), $1574\left(\mathrm{NO}_{2}, \mathrm{~m}\right), 1383\left(\mathrm{NO}_{2}, \mathrm{~m}\right), 1268(\mathrm{~m})$, $720(\mathrm{~m})$. ESI-MS: $159\left(\mathrm{M}^{+}\right)$. Anal. Calcd for $\mathrm{C}_{3} \mathrm{H}_{2} \mathrm{~N}_{4} \mathrm{O}_{4}$ : C, 22.78; H, 1.26; N, 35.43. Found: C, $22.52 ; \mathrm{H}, 1.41 ; \mathrm{N}, 35.40$. The IR characterization data agree with those reported. ${ }^{20}$

### 5.6.2 Methyl imidazole-4-carboxylate

This compound was prepared by modifying a reported procedure used to synthesize the analogous ethyl ester. ${ }^{23}$ To a suspension of imidazole-4-carboxylic acid $(1.00 \mathrm{~g}, 8.92 \mathrm{mmol})$ in $\mathrm{MeOH}(20 \mathrm{~mL})$ was added conc. $\mathrm{H}_{2} \mathrm{SO}_{4}(1.5 \mathrm{~mL})$. The mixture was refluxed for 24 h , at which point the solid was completely dissolved and TLC
showed the absence of the carboxylic acid. The solution was then cooled to $0{ }^{\circ} \mathrm{C}$ and neutralized to pH 8 using 5 M NaOH . The solvent was removed under vacuum and the white residue redissolved in a minimal volume of boiling water. White crystals of the ester formed when the aqueous solution was cooled. After standing for 1 h , the mixture was filtered, and the crystals were washed with cold $\mathrm{H}_{2} \mathrm{O}(1 \times 5 \mathrm{~mL})$. The solid was then dried under vacuum at r.t. for 24 h . Yield: $0.87 \mathrm{~g}(77 \%) .{ }^{1} \mathrm{H}$ NMR (dmso- $d_{6}$ ): $\delta 7.74$ (s, $1 \mathrm{H}, \mathrm{H}_{5}-\mathrm{Im}$ ), 7.65 (s, $1 \mathrm{H}, \mathrm{H}_{2}-\mathrm{Im}$ ), 2.51 ( $\mathrm{s}, 3 \mathrm{H}, \mathrm{CH}_{3}-\mathrm{Im}$ ). IR ( KBr pellet): v 3105 ( $\mathrm{N}-\mathrm{H}, \mathrm{s}$ ), 2976, 2846 (C-H, m), 1619 (C=O, m), 1363 ( s$), 1156$ (m), $864(\mathrm{~m})$. FAB (+): $127\left(\mathrm{M}^{+}\right)$. Anal. Calcd for $\mathrm{C}_{5} \mathrm{H}_{6} \mathrm{~N}_{2} \mathrm{O}_{2}$ : C, 47.62; H, 4.76; N, 22.22. Found: C, 47.54; H, 4.85; N, 21.69.

### 5.6.3 Methyl 1-tritylimidazole-4-carboxylate

This compound was prepared by modifying a reported procedure used to synthesize the analogous ethyl ester. ${ }^{23}$ To a solution of methyl imidazole-4-carboxylate $(0.80 \mathrm{~g}, 6.3 \mathrm{mmol})$ in DMF $(20 \mathrm{~mL})$, under $\mathrm{N}_{2}$, was added trityl chloride ( $1.77 \mathrm{~g}, 6.35$ mmol ), and the mixture was stirred at r.t. for 10 min until solution was complete. $\mathrm{NEt}_{3}$ $(0.98 \mathrm{~mL}, 7.0 \mathrm{mmol})$ was then added, and the mixture stirred for 16 h at r.t. The contents were then poured over ice, and the mixture left standing for 5 min . The cold mixture was then filtered and the precipitate was washed with $\mathrm{H}_{2} \mathrm{O}(2 \times 5 \mathrm{~mL})$, and dried under vacuum at r.t. for 24 h . Yield: $2.01 \mathrm{~g}(86 \%) .{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta 7.65\left(\mathrm{~s}, 1 \mathrm{H}, \mathrm{H}_{5}\right.$ - Im$)$, 7.52 (s, 1H, $\mathrm{H}_{2}-\mathrm{Im}$ ), 7.03-7.36 (m, $15 \mathrm{H}, \mathrm{Ph}_{3} \mathrm{C}$ ), 2.42 ( $\mathrm{s}, 3 \mathrm{H}, \mathrm{CH}_{3}-\mathrm{Im}$ ). FAB (+): 369 $\left(\mathrm{M}^{+}\right), 243\left(\mathrm{CPh}_{3}\right)$. Anal. Calcd for $\mathrm{C}_{24} \mathrm{H}_{20} \mathrm{~N}_{2} \mathrm{O}_{2}: \mathrm{C}, 78.26 ; \mathrm{H}, 5.43 ; \mathrm{N}, 7.61$. Found: C , 78.35; H, 5.56; N, 7.37.

### 5.6.4 4-Hydroxymethyl-1-tritylimidazole

Method A. This compound was prepared using a modified literature procedure. ${ }^{23}$ To a solution of methyl 1-tritylimidazole-4-carboxylate ( $1.02 \mathrm{~g}, 2.72 \mathrm{mmol}$ ) in THF ( 15 mL ) at r.t. under $\mathrm{N}_{2}$ was added 5.50 mL of a 1.0 M diisobutylaluminum hydride (DibalH) solution in hexanes. The mixture was stirred for 1 h until the ester was no longer present by TLC. The mixture was then cooled to $0{ }^{\circ} \mathrm{C}$ and the following were slowly added in sequence: $\mathrm{H}_{2} \mathrm{O}(0.8 \mathrm{~mL}), 15 \%$ aq. $\mathrm{NaOH}(1.0 \mathrm{~mL})$, and $\mathrm{H}_{2} \mathrm{O}(0.8 \mathrm{~mL})$. The
mixture was then filtered, and the precipitate washed with THF ( $3 \times 10 \mathrm{~mL}$ ), and the filtrate and combined washings were then evaporated under vacuum. The residue was dissolved in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$; this solution was washed with $\mathrm{H}_{2} \mathrm{O}$ to remove any remaining inorganic salts and then the $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ layer evaporated under vacuum. The white product was scraped from the flask and dried for an additional 24 h at r.t. under vacuum. Yield: $0.41 \mathrm{~g}(44 \%)$.

Method B. To a solution of 4-(hydroxymethyl)imidazole ( $0.52 \mathrm{~g}, 5.3 \mathrm{mmol}$ ) in DMF ( 10 mL ), under $\mathrm{N}_{2}$, was added trityl chloride $(1.48 \mathrm{~g}, 5.30 \mathrm{mmol})$. This mixture was stirred for 10 min at which time the solids had dissolved, and then $\mathrm{NEt}_{3}(0.90 \mathrm{~mL}$, 6.4 mmol ) was added. This mixture was stirred for 16 h at r.t., then poured onto ice and left standing for 5 min . The resulting precipitate was collected, washed with $\mathrm{H}_{2} \mathrm{O}(2 \times 10$ mL ), and dried under vacuum at r.t. for 24 h . Yield: $1.53 \mathrm{~g}(85 \%)$.
${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta 7.39\left(\mathrm{~s}, 1 \mathrm{H}, \mathrm{H}_{2}\right.$ - Im ), $7.27-6.97\left(\mathrm{~m}, 15 \mathrm{H}, \mathrm{CPh}_{3}\right), 6.80(\mathrm{~s}, 1 \mathrm{H}$, $H_{5}$ - Im ), $4.62\left(\mathrm{~s}, 2 \mathrm{H},-\mathrm{CH}_{2} \mathrm{OH}\right)$. $\mathrm{FAB}(+): 341\left(\mathrm{M}^{+}\right), 243\left(\mathrm{CPh}_{3}\right)$. Anal. Calcd for $\mathrm{C}_{23} \mathrm{H}_{20} \mathrm{~N}_{2} \mathrm{O}: \mathrm{C}, 81.18 ; \mathrm{H}, 5.88 ; \mathrm{N}, 8.24$. Found: C, $81.24 ; \mathrm{H}, 5.91 ; \mathrm{N}, 7.87$. The ${ }^{1} \mathrm{H}$ NMR data agree with those reported. ${ }^{23}$

### 5.6.5 4-Hydroxymethyl-2-nitroimidazole

This compound was prepared according to a literature procedure. ${ }^{23}$ To a solution of 4-hydroxymethyl-1-tritylimidazole ( $0.99 \mathrm{~g}, 2.9 \mathrm{mmol}$ ) in THF ( 35 mL ) under $\mathrm{N}_{2}$ at 0 ${ }^{\circ} \mathrm{C}$ was added $4.05 \mathrm{~mL}(6.08 \mathrm{mmol})$ of a 1.5 M solution of $n-\mathrm{BuLi}$ in hexanes slowly over 1 min . The pale yellow solution, on being stirred for 2 h , became dark red and a white precipitate formed. $n$-Propyl nitrate $(0.64 \mathrm{~g}, 6.1 \mathrm{mmol})$ was then added and gave immediately a dark brown mixture that was stirred for 1 h . The solution was then cooled to $0^{\circ} \mathrm{C}$, diluted with $\mathrm{MeOH}(40 \mathrm{~mL})$, and then conc. $\mathrm{HCl}(5 \mathrm{~mL})$ was added to remove the trityl group and to hydrolyze any remaining traces of nitrate esters. This mixture was stirred for 12 h , and then the solvent was removed under vacuum. The residue was triturated with $20 \%$ aq. $\mathrm{EtOH}(10 \mathrm{~mL})$ and then filtered. The filtrate was evaporated leaving a brown solid that was then chromatographed on silica gel ( $\sim 80 \mathrm{~g}$ ). The column was first eluted with EtOAc to remove impurities and then with $5 \% \mathrm{MeOH}$ in EtOAc to elute the desired product. The fractions were analyzed by TLC, and those containing the
product were combined and evaporated, and the resulting solid was dried at r.t. for 24 h . Yield: $12 \mathrm{mg}(3 \%) .{ }^{1} \mathrm{H} \operatorname{NMR}\left(\mathrm{CD}_{3} \mathrm{OD}\right): \delta 7.15$ (s, $1 \mathrm{H}, \mathrm{H}_{5}$-Im), $4.50\left(\mathrm{~s}, 2 \mathrm{H},-\mathrm{CH}_{2} \mathrm{OH}\right)$. ESI-MS: $144\left(\mathrm{M}^{+}\right)$. The ${ }^{1} \mathrm{H}$ NMR data agree with those reported. ${ }^{23}$

### 5.6.6 Dimethyl imidazole-4,5-dicarboxylate

This compound was prepared according to a literature procedure. ${ }^{29,30}$ To a suspension of imidazole-4,5-dicarboxylic acid ( $5.03 \mathrm{~g}, 32.2 \mathrm{mmol}$ ) in MeOH ( 80 mL ) was added conc. $\mathrm{H}_{2} \mathrm{SO}_{4}(5 \mathrm{~mL})$. The mixture was refluxed for 6 h when the solid had dissolved to give a colorless solution; TLC showed the absence of the dicarboxylic acid. The solution was then cooled at $0{ }^{\circ} \mathrm{C}$ and neutralized to pH 8 using 5 M NaOH . The solvent was removed under vacuum and the white residue redissolved in a minimal volume of boiling water. A white precipitate separated when the solution was cooled. The white precipitate was collected, washed with cold $\mathrm{H}_{2} \mathrm{O}(1 \times 5 \mathrm{~mL})$, and dried under vacuum at r.t. for 24 h . Yield: $5.03 \mathrm{~g}(85 \%) .{ }^{1} \mathrm{H}$ NMR (dmso-d $\mathrm{d}_{6}$ : $\delta 7.89$ ( $\mathrm{s}, 1 \mathrm{H}, \mathrm{H}_{2}$-Im), $3.79\left(\mathrm{~s}, 6 \mathrm{H},-\mathrm{OCH}_{3}\right) . \mathrm{FAB}(+): 185\left(\mathrm{M}^{+}\right)$. Anal. Calcd for $\mathrm{C}_{7} \mathrm{H}_{8} \mathrm{~N}_{2} \mathrm{O}_{4}: \mathrm{C}, 45.65 ; \mathrm{H}, 4.35$; N, 15.22. Found: C, 45.42; H, 4.56; N, 15.01.

### 5.6.7 Dimethyl 1-tritylimidazole-4,5-dicarboxylate

This compound was prepared according to a literature procedure. ${ }^{29}$ To a solution of dimethyl imidazole-4,5-dicarboxylate ( $4.02 \mathrm{~g}, 21.8 \mathrm{mmol}$ ) in DMF ( 40 mL ) under $\mathrm{N}_{2}$ was added trityl chloride ( $6.09 \mathrm{~g}, 21.9 \mathrm{mmol}$ ), and $\mathrm{NEt}_{3}(3.05 \mathrm{~mL}, 21.9 \mathrm{mmol})$; the mixture was stirred at r.t. for 6 h when TLC revealed that none of the precursor dicarboxylate remained. The mixture was then poured over crushed ice and, after 10 $\min$, was filtered; the white precipitate was collected, washed with $\mathrm{H}_{2} \mathrm{O}(2 \times 10 \mathrm{~mL})$, and dried under vacuum at r.t. for 24 h . Yield: $6.61 \mathrm{~g}(71 \%) .{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta 7.55$ (s, $1 \mathrm{H}, \mathrm{H}_{2}$ - Im ), 7.37-7.17 (m, 15H, $\mathrm{CPh}_{3}$ ), $3.86\left(\mathrm{~s}, 3 \mathrm{H},-\mathrm{OCH}_{3}\right), 3.17\left(\mathrm{~s}, 3 \mathrm{H},-\mathrm{OCH}_{3}\right) . \mathrm{FAB}$ $(+): 427\left(\mathrm{M}^{+}\right), 243\left(\mathrm{CPh}_{3}\right)$. Anal. Calcd for $\mathrm{C}_{26} \mathrm{H}_{22} \mathrm{~N}_{2} \mathrm{O}_{4}: \mathrm{C}, 73.22 ; \mathrm{H}, 5.19 ; \mathrm{N}, 6.57$. Found: C, 73.27; H, 5.23; N, 6.41.

### 5.6.8 4,5-Dihydroxymethyl-1-tritylimidazole

This compound was prepared according to a modified literature procedure. ${ }^{29}$ To a solution of dimethyl 1-tritylimidazole-4,5-dicarboxylate ( $1.03 \mathrm{~g}, 2.41 \mathrm{mmol}$ ) in THF ( 20 mL ) at r.t. under $\mathrm{N}_{2}$ was added 10.5 mL of a 1.0 M Dibal-H solution in hexanes. The mixture was stirred for 4 h , when the TLC band for the dicarboxylate was no longer present. The mixture was cooled at $0^{\circ} \mathrm{C}$ and to it was added in sequence: $\mathrm{H}_{2} \mathrm{O}(1.5 \mathrm{~mL})$, $15 \%$ aq. $\mathrm{NaOH}(2 \mathrm{~mL})$, and $\mathrm{H}_{2} \mathrm{O}(1.5 \mathrm{~mL})$. The mixture was then filtered and the precipitate washed with warm THF ( $3 \times 10 \mathrm{~mL}$ ). The combined filtrate and washings were evaporated under vacuum, and the residue was dissolved in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$. This solution was filtered through Celite ( $\sim 10 \mathrm{~g}$ ) and the filtrate was evaporated. The resulting white solid was dried under vacuum at r.t. for 24 h . Yield: $0.42 \mathrm{~g}(44 \%)$. ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right)$ : $\delta 7.67\left(\mathrm{~s}, 1 \mathrm{H}, \mathrm{H}_{2}-\mathrm{Im}\right), 7.41-7.19\left(\mathrm{~m}, 15 \mathrm{H}, \mathrm{CPh}_{3}\right), 4.83\left(\mathrm{~s}, 2 \mathrm{H},-\mathrm{CH}_{2} \mathrm{OH}\right), 3.89(\mathrm{~s}, 2 \mathrm{H}$, $\left.\mathrm{CH}_{2} \mathrm{OH}\right)$. $\mathrm{FAB}(+): 371\left(\mathrm{M}^{+}\right), 243\left(\mathrm{CPh}_{3}\right)$. Anal. Calcd for $\mathrm{C}_{26} \mathrm{H}_{22} \mathrm{~N}_{2} \mathrm{O}_{4}: \mathrm{C}, 77.81 ; \mathrm{H}$, $5.99 ;$ N, 7.56. Found: C, 77.74; H, 5.91; N, 7.39.

### 5.6.9 $\mathrm{Ru}(\mathrm{pic})_{3} \cdot \mathrm{H}_{2} \mathrm{O}$ (30)

Method A. This method was modified from a literature procedure. ${ }^{3}$ Picolinic acid $(0.14 \mathrm{~g}, 1.2 \mathrm{mmol})$ was added to a red solution of $\mathrm{K}_{3}\left[\mathrm{RuCl}_{6}\right]$ (Section 2.4.4) ( 0.17 g , 0.39 mmol ) in 5 mL H O ; this was heated at $60^{\circ} \mathrm{C}$ for 5 h when a yellow precipitate slowly formed. The mixture was then cooled to r.t. before isolation of the solid by filtration; the solid was washed with $\mathrm{MeOH}(2 \times 5 \mathrm{~mL})$ and $\mathrm{H}_{2} \mathrm{O}(1 \times 5 \mathrm{~mL})$ and dried under vacuum at $78{ }^{\circ} \mathrm{C}$ for 48 h . Yield: $0.11 \mathrm{~g}(58 \%)$.

Method B. This method was performed as reported in the literature. ${ }^{4}$ Hpic $(0.096 \mathrm{~g}, 0.78 \mathrm{mmol})$ was added to a brown solution of $\left[\mathrm{Ru}_{2}\left(\mathrm{CH}_{3} \mathrm{COO}\right)_{4} \mathrm{Cl}\right](0.062 \mathrm{~g}$, $0.13 \mathrm{mmol})$ in water $/ \mathrm{MeOH}, 1: 1(10 \mathrm{~mL})$, and the mixture was refluxed for 8 h when a yellow precipitate formed. The reaction mixture was cooled to r.t. and the solid isolated by filtration, washed with $\mathrm{H}_{2} \mathrm{O}(2 \times 5 \mathrm{~mL})$, and dried under vacuum at $78{ }^{\circ} \mathrm{C}$ for 24 h . Yield: $0.049 \mathrm{~g}(77 \%)$.

IR ( KBr pellet): v $3443(\mathrm{O}-\mathrm{H}, \mathrm{s}), 1661\left(\mathrm{C}=\mathrm{O}_{\text {asym }}, \mathrm{s}\right), 1565(\mathrm{~m}), 1315\left(\mathrm{C}=\mathrm{O}_{\text {sym }}, \mathrm{m}\right)$, 1280 (s), 1057(m). ESI-MS: $468\left(\mathrm{M}^{+}\right)$. Anal. Calcd for $\mathrm{C}_{18} \mathrm{H}_{12} \mathrm{~N}_{3} \mathrm{O}_{6} \mathrm{Ru} \cdot \mathrm{H}_{2} \mathrm{O}: \mathrm{C}, 44.54 ; \mathrm{H}$, $2.89 ; \mathrm{N}, 8.65$. Found: C, $44.51 ; \mathrm{H}, 2.74 ; \mathrm{N}, 8.28$. The IR data agree with those reported. ${ }^{3,4}$

### 5.6.10 $\left[\mathrm{Ru}_{2}\left(\text { pic }^{2}\right)_{4}(\mathrm{EtOH}) \mathrm{Cl}\right] \cdot \mathrm{H}_{2} \mathrm{O}(31)$

Hpic ( $0.072 \mathrm{~g}, 0.59 \mathrm{mmol}$ ) was added to a brown solution of $\mathrm{RuCl}_{3} \cdot 3 \mathrm{H}_{2} \mathrm{O}(0.051$ $\mathrm{g}, 0.19 \mathrm{mmol}$ ) in 10 mL EtOH. This solution was refluxed for 6 h , the colour becoming red and finally bright orange. The solvent was reduced in volume to $\sim 1 \mathrm{~mL}$, when $\mathrm{Et}_{2} \mathrm{O}$ $(10 \mathrm{~mL})$ was added to give an orange precipitate that was collected, washed with $\mathrm{Et}_{2} \mathrm{O}(2$ $x 5 \mathrm{~mL}$ ), and then dried under vacuum at $78{ }^{\circ} \mathrm{C}$ for 24 h . Yield: $0.066 \mathrm{~g}(86 \%) .{ }^{1} \mathrm{H}$ NMR ( $\mathrm{D}_{2} \mathrm{O}$ ): $\delta 8.76-7.92$ (m, pic-H), 4.53 (br q, coordinated $\mathrm{HOCH}_{2} \mathrm{CH}_{3}$ ), 1.45 (br t, coordinated $\mathrm{HOCH}_{2} \mathrm{CH}_{3}$ ), 0.2 , -5.1 (br s, pic-H). IR ( KBr pellet): v $3468(\mathrm{O}-\mathrm{H}, \mathrm{s}), 3124$ $(\mathrm{N}-\mathrm{H}, \mathrm{m}), 1672\left(\mathrm{C}=\mathrm{O}_{\text {asym }}, \mathrm{s}\right), 1639\left(\mathrm{C}=\mathrm{O}_{\text {asym }}, \mathrm{s}\right), 1600(\mathrm{~m}), 1456(\mathrm{~m}), 1396\left(\mathrm{C}=\mathrm{O}_{\text {sym }}, \mathrm{m}\right)$, 1316 (C=O sym m), 1282 (m), 1147 (m), 856 (m), 759 (s), 691 (m). ESI-MS: 727 (M ${ }^{+}$EtOH), $382\left(\mathrm{Ru}(\text { pic })_{2} \mathrm{Cl}^{+}\right), 346\left(\mathrm{Ru}(\text { pic })_{2}{ }^{+}\right) . \quad \Lambda_{\mathrm{M}}(\mathrm{MeOH})=112 \Omega^{-1} \mathrm{~cm}^{2} \mathrm{~mol}^{-1}$. Anal. Calcd for $\mathrm{C}_{26} \mathrm{H}_{22} \mathrm{~N}_{4} \mathrm{O}_{9} \mathrm{ClRu}_{2} \cdot \mathrm{H}_{2} \mathrm{O}: \mathrm{C}, 39.52 ; \mathrm{H}, 3.04 ; \mathrm{N}, 7.09$. Found: C, 39.38; H, 2.89; N, 6.94.

### 5.6.11 Ru(Im-CO $\left.)_{2}\right)_{\mathbf{3}} \cdot \mathbf{2 \mathrm { H } _ { 2 } \mathrm { O }}$ (32)

Method A. Imidazole-4-carboxylic acid ( $\mathrm{Im}-\mathrm{CO}_{2} \mathrm{H}$ ) ( $0.094 \mathrm{~g}, 0.84 \mathrm{mmol}$ ) was added to a red solution of $\mathrm{K}_{3}\left[\mathrm{RuCl}_{6}\right](0.12 \mathrm{~g}, 0.28 \mathrm{mmol})$ in $\mathrm{H}_{2} \mathrm{O}(10 \mathrm{~mL})$. The resulting red solution was refluxed for 6 h to afford a yellow precipitate that was collected at r.t., washed with $\mathrm{MeOH}\left(2 \times 5 \mathrm{~mL}\right.$ ), and dried under vacuum at $78^{\circ} \mathrm{C}$ for 48 h . Yield: 0.074 $\mathrm{g}(57 \%)$.

Method B. $\operatorname{Im}-\mathrm{CO}_{2} \mathrm{H}(0.092 \mathrm{~g}, 0.82 \mathrm{mmol})$ was added to a brown solution of $\left[\mathrm{Ru}_{2}\left(\mathrm{CH}_{3} \mathrm{COO}\right)_{4} \mathrm{Cl}\right](0.065 \mathrm{~g}, 0.14 \mathrm{mmol})$ in water $/ \mathrm{MeOH}, 1: 1(10 \mathrm{~mL})$. The resulting brown solution was refluxed for 8 h to afford a yellow precipitate that was collected at r.t., washed with $\mathrm{MeOH}\left(2 \times 5 \mathrm{~mL}\right.$ ), and dried under vacuum at $78^{\circ} \mathrm{C}$ for 48 h . Yield: $0.043 \mathrm{~g}(67 \%)$
${ }^{1} \mathrm{H}$ NMR (dmso- $d_{6}$ ): $\delta 0.31,0.09,-0.09$ (s, H(5)-Im), -2.67, -13.55, -17.87 (s, H(2)-Im). IR (KBr pellet): v $3423(\mathrm{O}-\mathrm{H}, \mathrm{s}), 3109(\mathrm{~N}-\mathrm{H}, \mathrm{br} \mathrm{s}), 1642\left(\mathrm{C}=\mathrm{O}_{\text {asym }}, \mathrm{s}\right), 1324$ $\left(\mathrm{C}=\mathrm{O}_{\text {sym }}, \mathrm{s}\right), 1201(\mathrm{~m}), 1090(\mathrm{~m}), 1024(\mathrm{~m}), 930(\mathrm{~m}), 829(\mathrm{~m})$. ESI-MS: $435\left(\mathrm{M}^{+}\right)$. Anal. Calcd for $\mathrm{C}_{12} \mathrm{H}_{9} \mathrm{~N}_{6} \mathrm{O}_{6} \mathrm{Ru} \cdot 2 \mathrm{H}_{2} \mathrm{O}: \mathrm{C}, 30.63 ; \mathrm{H}, 2.77$; $\mathrm{N}, 17.87$. Found: C, 30.87; H, 2.58; N, 17.47.

### 5.6.12 $\mathrm{Ru}\left(\mathrm{Im}-\mathrm{CO}_{2}\right)\left(\mathbf{I m}-\mathrm{CO}_{2} \mathrm{H}\right)_{2} \mathrm{Cl}_{2} \cdot \mathbf{E t O H} \cdot \mathrm{H}_{2} \mathrm{O}$ (33)

Im $-\mathrm{CO}_{2} \mathrm{H}(0.084 \mathrm{~g}, 0.75 \mathrm{mmol})$ was added to a brown solution of $\mathrm{RuCl}_{3} \cdot 3 \mathrm{H}_{2} \mathrm{O}$ $(0.065 \mathrm{~g}, 0.25 \mathrm{mmol})$ in $\mathrm{EtOH}(10 \mathrm{~mL})$. The resulting solution was refluxed for 4 h , when it had become yellow. The solvent was reduced in volume to $\sim 2 \mathrm{~mL}$ and 15 mL of $\mathrm{Et}_{2} \mathrm{O}$ was added to afford a yellow precipitate that was collected, washed with $\mathrm{Et}_{2} \mathrm{O}(3 \times 5$ mL ), and dried under vacuum at $78{ }^{\circ} \mathrm{C}$ for 24 h . Yield: $0.11 \mathrm{~g}(76 \%) .{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CD}_{3} \mathrm{OD}\right): \delta 3.45\left(\mathrm{q}, \mathrm{HOCH}_{2} \mathrm{CH}_{3}\right), 1.12\left(\mathrm{t}, \mathrm{HOCH}_{2} \mathrm{CH}_{3}\right),-4.49,-7.20,-10.16(\mathrm{~s}, \mathrm{H}(5)-\mathrm{Im})$, $-14.83,-16.75,-23.92$ ( $\mathrm{br} \mathrm{s}, \mathrm{H}(2)-\mathrm{Im}$ ). IR ( KBr pellet): v $3467(\mathrm{O}-\mathrm{H}, \mathrm{br}$ s), $3217(\mathrm{O}-\mathrm{H}$, m), 3149 ( $\mathrm{N}-\mathrm{H}, \mathrm{m}$ ), $1718\left(\mathrm{C}=\mathrm{O}_{\text {asym }}, \mathrm{s}\right), 1706\left(\mathrm{C}=\mathrm{O}_{\text {asym }}, \mathrm{s}\right), 1570\left(\mathrm{C}=\mathrm{O}_{\text {asym, }} \mathrm{s}\right), 1384$ $\left(\mathrm{C}=\mathrm{O}_{\text {sym, }} \mathrm{m}\right), 1350\left(\mathrm{C}=\mathrm{O}_{\text {sym }} \mathrm{m}\right), 1313\left(\mathrm{C}=\mathrm{O}_{\text {sym, }} \mathrm{m}\right), 1188(\mathrm{~m}), 1089(\mathrm{~m})$. ESI-MS: 508 $\left(\mathrm{M}^{+}\right), 472\left(\mathrm{M}^{+}-\mathrm{Cl}\right), 396\left(\mathrm{M}^{+}-\mathrm{Im}-\mathrm{CO} 2 \mathrm{H}\right), 360\left(\mathrm{M}^{+}-\mathrm{Im}-\mathrm{CO} 2 \mathrm{H}-\mathrm{Cl}\right) . \Lambda_{\mathrm{M}}(\mathrm{MeOH})=19$ $\Omega^{-1} \mathrm{~cm}^{2} \mathrm{~mol}^{-1}$. Anal. Calcd for $\mathrm{C}_{12} \mathrm{H}_{11} \mathrm{~N}_{6} \mathrm{O}_{6} \mathrm{Cl}_{2} \mathrm{Ru} \cdot \mathrm{EtOH} \cdot \mathrm{H}_{2} \mathrm{O}: \mathrm{C}, 29.42 ; \mathrm{H}, 3.33 ; \mathrm{N}, 14.71$. Found: C, 29.36; H, 3.17; N, 14.44.

## Chapter 6

## Antiproliferatory Activity of Ruthenium Complexes Using the MTT Assay

### 6.1 Introduction

For preliminary drug screening, tumour cell lines are used to test the antiproliferatory activity of compounds in vitro. Compounds then showing activity can be tested in vivo to determine if the in vivo and in vitro properties correlate. The MTT assay is a colourimetric assay commonly used as a screening process to examine the antiproliferatory activity of compounds over large concentration ranges. ${ }^{1}$ The assay quantifies the extent of 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) reduction to formazan by mitochondrial dehydrogenase (Figure 6.1). In viable cells (Figure 6.2), MTT (yellow) is reduced to formazan (purple) which precipitates onto the surface of the wells. Dissolving the precipitate in DMSO gives a purple solution (Figure 6.3, details of the procedure are given in Section 6.3, as well as in a recent publication by our group ${ }^{2}$ ). The amount of formazan in each well is then measured spectrophotometrically to determine the number of viable cells in each well. The absorbance values at determined at each concentration are then divided by the absorbance values of the control and plotted vs. concentration. From these graphs, $\mathrm{IC}_{50}$ values can be

Figure 6.1 Mitochondrial reduction of MTT to Formazan.

Figure 6.2 Pictures of cells on Day 5 of MTT assay before adding MTT in a control experiment with no complex (left), and in an experiment incubated for 69 h in $2 \mathrm{mM} \mathrm{Ru}(\mathrm{ma})_{3}$ (right).

Day 1 - Plate cells
Day 5 - Read plate

Figure 6.3 Outline of MTT assay from Day 1 - Day 5; see Section 6.3. The outer rows of wells are filled with water, and the inner wells with cells increasing in concentration of complex from right to left. The leftmost two columns are the blank (farthest left) and control (second from left). The intensity of the purple colour is proportional to the number of viable cells present (highest for the control and low concentration samples).
determined, the concentration at which the number of viable cells is $50 \%$ that of the control. ${ }^{3,4}$ Low $\mathrm{IC}_{50}$ values with respect, in particular, to that of cisplatin ( $40 \mu \mathrm{M}$ for the MDA-MB-435S cell line under the reaction conditions described in this Section 6.3, Table 6.4), are desirable and suggest that the compound is having an antiproliferatory effect at low concentrations. ${ }^{5}$ Complexes exhibiting high $\mathrm{IC}_{50}$ values may also have useful biological applications, particularly in the case of EF5 complexes (Table 6.3), which may be specific to hypoxic cells. ${ }^{6}$ There is a need to develop useful imaging agents for hypoxia that should specifically target hypoxic cells while, at the same time, be
free of any cytotoxic effects that might also harm healthy cells (i.e. exhibit high $\mathrm{IC}_{50}$ values). ${ }^{7}$

The results of the MTT assay have been found generally to correlate well with in vivo studies as well as with other in vitro studies such as the dye exclusion assay. ${ }^{8}$ Measurements of formazan absorption in MTT tests have been shown to correlate very well with the number of counted cells both using a Coulter counter ${ }^{3}$ and using microscopic counting techniques. ${ }^{9,10}$ Like all assays, however, results from the MTT assay vary between cell lines and, within a given cell line, results may vary from week to week (Section 6.4.2, $\pm 5 \%$ ) although this variation can often be difficult to distinguish from the natural distribution of the data. ${ }^{11}$ For these reasons the MTT assay is only a preliminary assay. Positive results at this stage then lead to more detailed testing in vitro using more cell lines as well as in vivo studies.

Experience in the development of NAMI-A (Figure 1.8, Section 1.5.3.1) has led to a set of suggested guidelines for the testing of Ru complexes for anti-cancer properties. The Callerio Foundation, the group responsible for the development of NAMI-A, lists the MTT assay as the first step in a screening process recommended for determining whether a Ru complex may exhibit any antiproliferatory activity toward a given cancer cell line. ${ }^{5}$

### 6.2 General Experimental Procedures

### 6.2.1 Experimental Media, Solutions, and Materials

Leibovitz's L-15 medium with L-glutamine (L-15), Dubelco's modified essential medium (DMEM), fetal bovine serum (FBS), zinc bovine insulin, penicillin/streptomycin antibiotic, phosphate buffered saline solution 7.4 (PBS), and trypsin-EDTA ( $0.25 \%$ trypsin in $1 \mathrm{mM} \mathrm{Na}_{4}($ EDTA $)$ ) were purchased from Gibco. 96 -Well plates, T-25 and T-75 flasks were purchased from Falcon. MTT was purchased from Aldrich. The growth medium for the MDA-MB-435S cell line consisted of 500 mLL - 15 , 50 mL FBS, and 5.0 mg of insulin. The growth medium for the MDA435/LCC6-WT cell line consisted of 500 mL DMEM, 50 mL FBS, and 5,000 units of penicillin/streptomycin antibiotic. PBS, MTT and the growth medium were stored at $4{ }^{\circ} \mathrm{C}$, while the trypsin-EDTA and FBS were stored at $-20^{\circ} \mathrm{C}$. FBS was filter-sterilized through $0.1 \mu \mathrm{~m}$ filters before use.

### 6.2.2 Cell Preparation

Human breast cancer cells (MDA-MB-425S) were purchased from the American Type Tissue Culture Collection (ATCC), while MDA435/LCC6-WT cells ${ }^{12,13}$ were kindly donated by Dr. K Skov of the BC Cancer Research Center. The MDA-MB-435S cells were maintained in L-15 medium in T-75 tissue culture flasks at $37{ }^{\circ} \mathrm{C}$ under air. The cells were transferred every 3-4 days to new flasks at a dilution factor of approximately 8. Before transfer, the medium was removed from the flask, and the cells were rinsed for 20 s with 2 mL trypsin-EDTA, which was then removed and 2 mL of fresh trypsin-EDTA were added to the flask. After 3-4 min the cells were observed to detach from the flask surface, and 8 mL of medium were added. The cells were then counted under a microscope using a hemacytometer (Hausser Scientific, 0.100 mm deep). $2 \times 10^{6}$ cells (typically in 2-3 mL of medium) were then transferred to a T-75 flask, and the suspension diluted to 20 mL with medium to yield a final density of $1 \times 10^{5}$ cells $/ \mathrm{mL}$.

For the MDA435/LCC6-WT cells, the cell preparation was the same as for the MDA-MB-435S cells using DMEM medium in place of L-15 medium (the preparation of the media is described in Section 6.2.1).

### 6.2.3 Preparation of Ru Complexes

The Ru complexes were weighed into glass vials and dissolved in PBS to make 1.5 mL of 4 mM stock solutions for each complex. These solutions were then sonicated and heated to $37{ }^{\circ} \mathrm{C}$ to ensure the complex was completely dissolved, and then filtered through $0.2 \mu \mathrm{~m}$ filters to remove any remaining particulates. From this stock solution, subsequent dilutions yielded the following final concentrations: $2,1,0.5,0.2,0.1,0.05$, $0.02,0.01 \mathrm{mM}$ (Section 6.3.2). Follow-up experiments for several compounds focused on a lower concentration range, and thus stock solutions of 0.400 mM were used instead and the dilutions were adjusted to test concentrations as low as 500 nM . For the complexes containing EF5 (14), $2 \mathrm{NO}_{2} \operatorname{Im}$ (15) and $3 \mathrm{NO}_{2}$ tri (17), stock solutions of 4 mM could not be prepared because of poor complex solubilities in PBS. Instead 2 mM stock solutions of $\mathbf{1 5}$ and 17 were prepared in $20 \%$ DMSO in PBS, while a 2 mM solution of 14 was prepared in $5 \%$ DMSO in PBS. These three solutions were then heated to $50^{\circ} \mathrm{C}$
to ensure complete solubility of the complexes, filter sterilized while hot, and then cooled to room temperature before use.

### 6.2.4 Preparation of Ligand Precursor Solutions

Hma, HEma, DMSO and N-heterocyclic compounds (see Table 6.2) that acted as ligand precursors were tested over a concentration range from 5 to 0.02 mM . They were weighed into glass vials and dissolved in PBS to yield 1.5 mL of 10 mM stock solutions for each compound.

### 6.3 MTT Assay Procedure

### 6.3.1 Day 1 - Plating Cells

On day one of the MTT assay, cells were plated into 96 -well plates. The medium was removed from a T-75 flask containing the cells, and 2 mL of trypsin-EDTA were then added. The flask was gently agitated to rinse the cells. The trypsin-EDTA was removed and an additional 2 mL were added to the flask which was then sealed for 3-4 min . After 3 min the cells were examined under a microscope to determine whether they were still adhering to the plastic flask or whether they had become detached. If the cells were still adhering, the flask was again gently shaken to assist in the removal of the cells from the flask wall. L-15 medium ( 8 mL ) was then added to the flask. This suspension was thoroughly mixed by pipetting the mixture "up and down" several times. A $50 \mu \mathrm{~L}$ aliquot of the suspension were then removed and plated onto a hemacytometer to determine the cell count. Then the dilution factor needed to make a stock suspension of 1 $\times 10^{5}$ cells $/ \mathrm{mL}$ was calculated ( 5.4 mL of this suspension are required per plate), and 100 $\mu \mathrm{L}$ of this suspension were then added to each of the wells in columns 3-11 in rows B-G (Figure 6.4). Medium ( $100 \mu \mathrm{~L}$ ) was added to the wells in column 2 rows B-G (blank). Water ( $200 \mu \mathrm{~L}$ ) was then added to all the remaining wells to help prevent evaporation of the medium from the experimental wells. The plates were then placed into the incubator for 24 h .

Figure 6.4 Experimental 96-well plate set-up showing the control column (dark grey), the blank (white), the wells with water (light grey) and those containing the complex solutions (speckled).

### 6.3.2 Day 2 - Addition of Ru Complexes and Ligand Precursors

The 96-well plates were removed from the incubator after 24 h . Stock solutions of Ru complexes were prepared as described in Section 6.2.3. Dilutions of such stock solutions were then prepared in $700 \mu \mathrm{~L}$ tubes using PBS (except for $\mathbf{1 4}, \mathbf{1 5}$, and $\mathbf{1 7}$, see below), in order to yield eight $650 \mu \mathrm{~L}$ solutions spanning, when using a 4 stock solution, from 4 mM to 0.02 mM (Table 6.1). For those experiments in which a 0.4 mM stock solution was used, the concentrations of the corresponding diluted solutions were one order of magnitude less; in some cases different dilutions were used in order to test concentrations below $2 \mu \mathrm{M}$. The diluted solutions for all experiments were mixed using a multi-channel pipette and then $100 \mu \mathrm{~L}$ of each solution was pipetted into the wells in rows B-G and columns 2-11 (Figure 6.4). Only PBS (or PBS/DMSO in some cases, as discussed later below) was added to columns 2 and 3, as these two columns were the blank and control, respectively.

Solutions of $\mathbf{1 4}, \mathbf{1 5}$, and $\mathbf{1 7}$ were prepared as DMSO/PBS solutions and were thus subsequently diluted with the same solvent mixture used for their preparation (20 \% DMSO for $\mathbf{1 5}$ and 17, and $5 \%$ DMSO for 14) to ensure that any DMSO effect would be
minimized. In Section 3.3.3, it was observed that both 15 and 17 in DMSO dissociated ligands; however, the resulting solutions of these complexes in DMSO:PBS (1:1) were still tested using the MTT assay. The DMSO:PBS solvent mixtures were added to the control and blank to ensure that any DMSO effect would manifest itself in the control as well. The stock solutions of these three complexes were only 2 mM (see Section 6.2.3), and therefore the final concentrations of the diluted samples were half those shown in Table 6.1, which shows the final concentrations for samples diluted from a 4 mM stock solution.

Table 6.1 Dilution table for the addition of complexes using a 4 mM stock solution. ${ }^{\text {a }}$ Solutions of $650 \mu \mathrm{~L}$ were made for each concentration of Ru complex, as well as those for the blank and the control.

| Column | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Concentration of <br> complexes $(\mu \mathrm{M})$ | 0 | 0 | 4000 | 2000 | 1000 | 400 | 200 | 100 | 40 | 20 |
| Vol. PBS $(\mu \mathrm{L})$ | 650 | 650 | 0 | 325 | 487.5 | 585 | 617.5 | 633.75 | 643.5 | 646.75 |
| Vol. stock solution <br> $(\mu \mathrm{L})$ | 0 | 0 | 650 | 325 | 162.5 | 65 | 32.5 | 16.25 | 6.5 | 3.25 |

${ }^{\text {a }}$ For some complexes different stock solution concentrations or different dilution factors were used to perform the assay (see Sections 6.2.3 and 6.2.4).

For the ligand precursors, 10 mM stock solutions were prepared in PBS, the samples then being diluted in PBS to final concentrations spanning 10 to $50 \mu \mathrm{M}$. The dilutions used were as for the Ru complexes (Table 6.1), with the final concentrations being 2.5 times greater than those shown, as 10 mM stock solutions were used instead of 4 mM ones.

### 6.3.3 Day 5 - Addition of MTT and Plate Reading

A modified version of a published procedure was used for the addition of MTT. ${ }^{14}$ After incubation of the cell/complex mixture for $69 \mathrm{~h}, 50 \mu \mathrm{~L}$ of an MTT solution (2.5 $\mathrm{mg} / \mathrm{mL}$ in PBS) were added to each of the wells in rows B-G, columns 2-11. The plates were then incubated for an additional 3 h , at which time the medium was removed from all the wells to leave purple formazan crystals. DMSO ( $150 \mu \mathrm{~L}$ ) was then added to each
of the columns in rows B-G, columns 2-11, and the plates were then scanned at 570 nm on a Spectra Max 190 Elisa plate reader (Molecular Devices Co.) with a shake time set to 10 s before reading the plates (Figure 6.5). Values for the blank absorbance were averaged and automatically subtracted from those read for each well using Softmax Pro v2.2.1 software.

### 6.3.4 Data Analysis

For each compound, six replicates were performed at each of eight different concentrations. The absorbance of each well at 570 nm was determined. The values obtained were normalized by subtracting the average absorbance value for the 6 blank replicates from the value for each experimental and control well. At each concentration the average absorbance over the 6 replicates was determined and divided by the average value for the 6 control replicates to determine the percent cell viability at each concentration. Values presented in this chapter are the $\mathrm{IC}_{50}$ values determined by graphing the percent viability versus concentration, and for the complexes are the average value as determined from two or more experiments. For the free ligands, the $\mathrm{IC}_{50}$ values reported are those from a single experiment. With the MDA-MB-435S cell line, $\mathrm{IC}_{50}$ values were found to be reproducible within experimental uncertainty from week to week. Error bars are included on each graph and represent 2 standard deviations or a 95 \% confidence limit.

Figure 6.5 Image of plate after MTT treatment. The control is clearly seen as a purple column on the left, and the purple colours on the right clearly show the increase in cell viability at lower concentration.

### 6.4 Results and Discussion

### 6.4.1 Ligand Precursors

Table 6.2 shows the $\mathrm{IC}_{50}$ values for the ligand precursors used to form the Ru complexes that were tested. The only one of these compounds that showed significant activity was $2 \mathrm{NO}_{2} \mathrm{Im}$, exhibiting an $\mathrm{IC}_{50}$ value of $50 \mu \mathrm{M}$. Only two other compounds exhibited $\mathrm{IC}_{50}$ values below $500 \mu \mathrm{M}$, EF5 and $3 \mathrm{NO}_{2}$ tri, both N -heterocycles containing a

nitro group. The lack of any significant activity of ma, Ema and most of the imidazoles $\left(\mathrm{IC}_{50}\right.$ values are much higher than those observed for complexes containing these compounds as ligands, see Section 6.4.2) suggests that the lower $\mathrm{IC}_{50}$ values for the complexes are not a result of dissociated ligand inside the cell.

### 6.4.2 Ru Maltolato and Imidazole Complexes

In total, 23 complexes were screened using the MTT assay (Tables 6.3-6.6). Because of some variability in the assay from week to week resulting from changes in cell morphology over time, $\mathrm{Ru}(\mathrm{ma})_{3}(\mathbf{1})$ and $\left[\mathrm{Ru}(\mathrm{ma})_{2}(2 \mathrm{MeIm})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}(\mathbf{1 0})$ were used as standards to ensure consistency from week to week. These complexes were chosen as they exhibited activity in different concentration ranges ( $\mathrm{IC}_{50}$ value for $\mathbf{1}$ is $140 \mu \mathrm{M}$ and for 10 is $5 \mu \mathrm{M}$ ), and showed similar variability from week to week (e.g. if the $\mathrm{IC}_{50}$ value for 1 went up $5 \%$, so did the $\mathrm{IC}_{50}$ value for $\mathbf{1 0}$; in general, weekly variability was $<5 \%$ and thus values non-normalized values still fell within experimental error limits); in contrast, the activity of cisplatin, did not vary. Cisplatin was also tested and used as a control to help compare the results with those of other groups, who have used different cell lines but have used cisplatin as a standard. ${ }^{15}$ The tests with the free ligands (Table 6.2) suggest that the intact complexes in solution likely give rise to the activity and not free ligand present as a result of ligand dissociation over the incubation period. Table 6.3 shows the $\mathrm{IC}_{50}$ values for the maltolato complexes that were tested. Only 3 complexes with nitro-substituted ligands were tested because of poor solubilities in PBS. In fact, at higher complex concentrations, the 570 nm absorbances for the complexes with EF5 (14), $2 \mathrm{NO}_{2} \mathrm{Im}$ (15) and $3 \mathrm{NO}_{2}$ tri (17) increased as a result of metal-containing species precipitating from the reaction medium. This was confirmed by examining the cells under a microscope on day 5 of the MTT assay, before the addition of MTT. Under the microscope, blue solids for 15 and 17 , and a brown solid for 14 , were observed at concentrations of $500 \mu \mathrm{M}$ and higher.

Against the MDA-MB-435S cell line, $\left[\mathrm{Ru}(\mathrm{ma})_{2}(2 \mathrm{MeIm})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$ (10) showed the lowest $\mathrm{IC}_{50}$ value of all the maltolato complexes tested ( $5 \mu \mathrm{M}$ ) (Figure 6.6); $\left[\mathrm{Ru}(\mathrm{ma})_{2}(4 \mathrm{MeIm})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3} \cdot \mathrm{CH}_{2} \mathrm{Cl}_{2}(6)$ was also highly active ( $15 \mu \mathrm{M}$ ). The next most

[^1]

Figure 6.6 Cell viability vs. concentration for $\left[\mathrm{Ru}(\mathrm{ma})_{2}(2 \mathrm{MeIm})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}(\mathbf{1 0})$, with error bars representing $95 \%$ confidence limit.
active imidazole complexes were the corresponding Im (7) and 1MeIm (8) species with $\mathrm{IC}_{50}$ values of 70 and $80 \mu \mathrm{M}$, respectively. These complexes ( $\mathbf{6}, 7,8$, and $\mathbf{1 0}$ ) showed no signs of ligand dissociation or reactivity in the PBS/medium solutions as judged by TLC analysis of the complex solutions after 5 days. This suggests that the intact complexes are responsible for the observed activity, and not a new complex resulting from partial ligand dissociation or displacement in the medium.
$\left[\mathrm{Ru}(\mathrm{ma})_{2}\left(2 \mathrm{NO}_{2} \mathrm{Im}\right)_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}(\mathbf{1 5})$ exhibited an $\mathrm{IC}_{50}$ value of $25 \mu \mathrm{M}$, half that of free $2 \mathrm{NO}_{2} \mathrm{Im}$ (Tables 6.2 and 6.3), the activity likely resulting from the presence of free $2 \mathrm{NO}_{2} \mathrm{Im}$, as TLC analysis of $\mathbf{1 5}$ dissolved in PBS:DMSO (1:1) showed a large band for this compound. The $25 \mu \mathrm{M} \mathrm{IC}_{50}$ value for 15 perhaps indicates that all of the $2 \mathrm{NO}_{2} \mathrm{Im}$ is dissociating, thus exhibiting an $\mathrm{IC}_{50}$ value half that observed for the free ligand ( $25 \mu \mathrm{M}$ complex is equiv. to $50 \mu \mathrm{M}$ free ligand). If the $2 \mathrm{NO}_{2} \mathrm{Im}$ is only partially dissociating in solution, the activity observed may be attributed to remaining undissociated Ru complex. The PBS/medium solution of the bis(EtOH) complex, 3, changed colour from red to green over the 3 day incubation, likely as a result of displacement of the EtOH ligands; EtOH is readily displaced by water at room temperature but the aqua complex is also red in colour (Section 3.2.3). The green colour suggests components of the PBS/medium solution are coordinating to the Ru .

Some of the complexes listed in Table 6.3 were also tested against another cell line, MDA435/LCC6 -WT, ${ }^{16}$ and the $\mathrm{IC}_{50}$ values differed from those observed against the MDA-MB-435S cell line for most of the complexes; 4,7 , and $\mathbf{8}$ exhibited $\mathrm{IC}_{50}$ values $>2 \mathrm{mM}$ against the MDA435/LCC6-WT cell line, compared to values of $70-80 \mu \mathrm{M}$ against the MDA-MB-435S cell line. Only the $\mathrm{IC}_{50}$ value for $\mathbf{1 0}$ was the same against both cell lines $(5 \mu \mathrm{M})$.
$\mathrm{Ru}(\mathrm{ma})_{3}(\mathbf{1})$ (Figure 6.7) and $\mathrm{Ru}(\mathrm{Ema})_{3}$ (2) (Figure 6.8) gave $\mathrm{IC}_{50}$ values of 140 and $90 \mu \mathrm{M}$, respectively, against the MDA-MB-435S cell line (Table 6.4); the values agree with those reported earlier against this cell line under similar conditions (150 and $80 \mu \mathrm{M}$ ). ${ }^{17}$ The increase in cell proliferation observed at lower concentration for 2 (at $<50 \mu \mathrm{M}$, Figure 6.8) was reproducible, suggesting that $\mathbf{2}$ has an advantageous effect on
cell proliferation at such concentrations as well as a deleterious one at higher concentrations.

Figure 6.7 Cell viability vs. concentration for $\mathrm{Ru}(\mathrm{ma})_{3}(\mathbf{1})$, with error bars representing $95 \%$ confidence limit.

${ }^{\text {a }}$ Error limits are $\pm 5 \%$ for cisplatin.
${ }^{\mathrm{b}}$ Error limits are $\pm 10 \%$ for the Ru complexes.

To determine if this trend of greater activity for Ema complexes (vs. ma species) was more general, Ema-4MeIm and -2MeIm derivatives were synthesized because 6 and 10 showed the lowest $\mathrm{IC}_{50}$ values of the ma complexes (Table 6.3). Again, the Ema systems exhibited lower $\mathrm{IC}_{50}$ values (Table 6.5): indeed, $\left[\mathrm{Ru}(\mathrm{Ema})_{2}(2 \mathrm{MeIm})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$ has an $\mathrm{IC}_{50}$ value of 500 nM (Figure 6.9), an order of magnitude lower than that of any other complex tested. It is unclear why the Ema derivatives exhibit $\mathrm{IC}_{50}$ values lower than those of the corresponding ma complexes, but this finding will be discussed further with other results given in Chapter 7.

Table 6.5 $\quad \mathrm{IC}_{50}$ values for ethylmaltolato complexes against MDA-MB-435S cells in L-15 medium after incubation at $37^{\circ} \mathrm{C}$ for $69 \mathrm{~h} .{ }^{\text {a }}$

Figure 6.9 Cell viability vs. concentration for $\left[\mathrm{Ru}(\mathrm{Ema})_{2}(2 \mathrm{MeIm})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}(\mathbf{1 3})$, with error bars representing $95 \%$ confidence limit.

Cisplatin was tested several times against the MDA-MB-435S cell line in order to provide a "known standard," and had an $\mathrm{IC}_{50}$ value of $40 \mu \mathrm{M}$ (Figure 6.10, Table 6.4), while the value against the human ovarian cell line A2780 is reported as $0.5 \mu \mathrm{M},{ }^{15}$ eighty times lower. $\mathrm{IC}_{50}$ values are also reported for $\mathrm{RuX}(p$-cymene) $(\mathrm{N}-\mathrm{N})$ complexes, where X $=\mathrm{Cl}$ or I and $\mathrm{N}-\mathrm{N}=$ ethylenediamine or $\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{2}$, against the A2780 cell line, some exhibiting $\mathrm{IC}_{50}$ values as low as $8 \mu \mathrm{M}$. ${ }^{15}$ Previously in our group, Huxham et al. found that $[\mathrm{RuCl}(p \text {-cymene })]_{2}(\mu$-BESE $)$ exhibited an $\mathrm{IC}_{50}$ value of $350 \mu \mathrm{M}$ against the MDA-MB-435S breast cancer cell line. ${ }^{18}$ As no one has reported on the biological activity of the precursor for these Ru - $p$-cymene complexes, $\left[\mathrm{Ru}(p \text {-cymene }) \mathrm{Cl}_{2}\right]_{2}$, this dimer was tested against the MDA-MB-435S breast cancer cell line and its $\mathrm{IC}_{50}$ was also found to be $350 \mu \mathrm{M}$ (Table 6.4). Per Ru atom, the $\mathrm{IC}_{50}$ values of both the starting dimer and $[\mathrm{RuCl}(\mathrm{p}-\mathrm{cymene})]_{2}(\mu$-BESE $)$ are $700 \mu \mathrm{M}$; thus the presence of the chelated sulfoxide is not necessary to produce the observed activity for this complex. ${ }^{18}$

Figure 6.10 Cell viability vs. concentration for cisplatin, with error bars representing $95 \%$ confidence limit. This experiment was done over a shortened concentration range to produce more points near the $\mathrm{IC}_{50}$ value and improve the accuracy of the assay.

### 6.4.3 Ru 4,4'-Biimidazole Complexes

Complexes of 4,4'-biimidazoles were also tested using the MTT assay, including maltolato biimidazole complexes (Table 6.6). After a 2 MeIm derivative was shown to exhibit the lowest $\mathrm{IC}_{50}$ value of a series of Ru-ma complexes (Table 6.3), 2,2'-dimethyl-4,4'-biimidazole ( $\mathrm{Me}_{2}$ biim) was synthesized (Section 4.8) as well as $4,4^{\prime}$ '-biimidazole (biim) (Section 4.8), and a Ru ma complex of each was examined, as well as other complexes containing either of these two ligands.

The $\mathrm{IC}_{50}$ value for $\left[\mathrm{Ru}(\mathrm{ma})_{2}\left(\mathrm{Me}_{2} \mathrm{biim}\right)\right] \mathrm{CF}_{3} \mathrm{SO}_{3} \cdot 2 \mathrm{H}_{2} \mathrm{O}$ (25) (Figure 6.11) is 15 $\mu \mathrm{M}$, the same as for 6 (Table 6.3), while $\left[\mathrm{Ru}(\mathrm{ma})_{2}(\right.$ biim $\left.)\right] \mathrm{CF}_{3} \mathrm{SO}_{3} \cdot 2 \mathrm{H}_{2} \mathrm{O}$ (24) (Figure 6.12) exhibited an $\mathrm{IC}_{50}$ value of $50 \mu \mathrm{M}$. These two complexes exhibit activities different from those of the analogous bis(Im) $\left(7, \mathrm{IC}_{50}=70 \mu \mathrm{M}\right)$ and $\operatorname{bis}(2 \mathrm{MeIm})\left(\mathbf{1 0}, \mathrm{IC}_{50}=5 \mu \mathrm{M}\right)$ complexes (Table 6.3). Two major differences that may account for this are the

Table 6.6 $\mathrm{IC}_{50}$ values ${ }^{\mathrm{a}}$ for biim and Me $\mathrm{C}_{2}$ biim complexes against MDA-MB-435S cells in L- 15 medium after incubation at $37^{\circ} \mathrm{C}$ for 69 h ; data for new Ru complexes containing picolinic acid (Hpic) or imidazole-4-carboxylic acid ( $\mathrm{Im}-\mathrm{CO}_{2} \mathrm{H}$ ) against the same cell line under the same conditions are also shown.

| Complex | $\mathrm{IC}_{50}(\mu \mathrm{M})$ |
| :---: | :---: |

| $\left[\mathrm{Ru}(\mathrm{ma})_{2}\left(\mathrm{Me}_{2} \mathrm{biim}\right)\right] \mathrm{CF}_{3} \mathrm{SO}_{3} \cdot 2 \mathrm{H}_{2} \mathrm{O}$ (25) | 15 |
| $\left[\mathrm{Ru}(\mathrm{biim})_{3}\right]\left[\mathrm{CF}_{3} \mathrm{SO}_{3}\right]_{2}$ (26) | 18 |
| $\left[\mathrm{Ru}\left(\mathrm{Me}_{2} \mathrm{biim}\right)_{3}\right]\left[\mathrm{CF}_{3} \mathrm{SO}_{3}\right]_{2}$ (27) | 36 |
| $\mathrm{RuCl}_{2}(\mathrm{DMSO})_{2}$ (biim) (20) | 800 |
| $\mathrm{RuCl}_{2}(\mathrm{DMSO})_{2}\left(\mathrm{Me}_{2} \mathrm{biim}\right)$ (22) | 400 |
| $\left[\mathrm{Ru}_{2}(\mathrm{pic})_{4}(\mathrm{EtOH}) \mathrm{Cl}\right] \cdot \mathrm{H}_{2} \mathrm{O}(\mathbf{3 1})$ | 100 |
| $\mathrm{Ru}\left(\mathrm{Im}-\mathrm{CO}_{2}\right)\left(\mathrm{Im}-\mathrm{CO}_{2} \mathrm{H}\right)_{2} \mathrm{Cl}_{2} \cdot \mathrm{H}_{2} \mathrm{O} \cdot \mathrm{EtOH}$ (33) | 400 |

[^3]geometric arrangement of the ligands (cis-ma for 24 and 25 vs. trans-ma for 7 and 10) and the $\mathrm{Ru}(\mathrm{II} / \mathrm{I})$ reduction potential in MeCN vs. $\mathrm{SCE}(-101$ and -35 mV for 24 and 25, respectively (Table 4.1), and -705 and -844 mV for 7 and 10, respectively (Table 3.4)). Clarke et al. have suggested that the reduction of $\mathrm{Ru}(I I I)$ to $\mathrm{Ru}(I I)$ may play an important role in the activation of Ru complexes inside the cell. ${ }^{19,20}$ The low reduction potentials of 7 and $\mathbf{1 0}$ perhaps indicate that such a reduction is not relevant for these two complexes. 24 and 25 , however, have much more positive reduction potentials and might be reduced inside the cell.

The cis geometry of the biimidazole complexes 24 and 25 compared to the trans geometry of all the complexes listed in Table 6.3 (Section 6.4.2) may also play an important role. The orientation of ligands can be important for their biological activity as in the case of cisplatin: the trans-isomer (trans- $\left[\mathrm{PtCl}_{2}\left(\mathrm{NH}_{3}\right)_{2}\right]$ ) is completely inactive because it is unable to form the necessary intrastrand DNA crosslinks to prevent cell division. ${ }^{21} 24$ and 25 appear to remain intact throughout the experiment (as judged by TLC), at least outside the cells. From the experiments conducted, it could not be

Figure 6.11 Cell viability vs. concentration for $\left[\mathrm{Ru}(\mathrm{ma})_{2}\left(\mathrm{Me}_{2} \mathrm{biim}\right)\right] \mathrm{CF}_{3} \mathrm{SO}_{3} \cdot 2 \mathrm{H}_{2} \mathrm{O}$ (25), with error bars representing $95 \%$ confidence limit.

Figure 6.12 Cell viability vs. concentration for $\left[\mathrm{Ru}(\mathrm{ma})_{2}(\mathrm{biim})\right] \mathrm{CF}_{3} \mathrm{SO}_{3} \cdot 2 \mathrm{H}_{2} \mathrm{O}$ (24), with error bars representing $95 \%$ confidence limit.
determined if an intra-cellular process might lead to any ligand dissociation. Even in the absence of vacant sites for binding components of intra-cellular molecules, the geometry of the ligands can still play a role in how the complexes interact with protein active sites: a transport protein, for example, may recognize only one of the cis- or trans-isomers.

Some $\mathrm{Ru}(\mathrm{II})$ complexes with biimidazoles were also tested (Table 6.6). The mixed biimidazole/DMSO complexes showed considerably less activity against this cell line than the $\mathrm{Ru}(\mathrm{III})$ complexes tested. Our group has reported on the activity of $\mathrm{Ru}(\Pi)$ maltolato sulfoxide complexes ${ }^{2}$ and $\mathrm{Ru}(\mathrm{I})$-acetylacetonato sulfoxide complexes ${ }^{22}$ against the MDA-MB-435S cell line (data taken from Wu's M.Sc. thesis), ${ }^{17}$ the lowest $\mathrm{IC}_{50}$ value being $190 \mu \mathrm{M}$ for $\mathrm{Ru}(\mathrm{Ema})_{2}(\mathrm{DMSO})_{2}$. $\left[\mathrm{Ru}\left(\mathrm{Me}_{2} \mathrm{biim}\right)_{3}\right]\left[\mathrm{CF}_{3} \mathrm{SO}_{3}\right]_{2} \quad(26)$ and $\left[\mathrm{Ru}(\mathrm{biim})_{3}\right]\left[\mathrm{CF}_{3} \mathrm{SO}_{3}\right]_{2}(27)$ exhibit $\mathrm{IC}_{50}$ values of 36 and $18 \mu \mathrm{M}$, respectively (Figures 6.13 and 6.14), which indicates significant antiproliferatory activity in the absence of the ma ligand, these complexes are almost certainly acting through a different mechanism than that of the Ru (III) ma complexes. No MTT studies have been reported using $\left[\mathrm{Ru}(\mathrm{Im})_{6}\right]\left[\mathrm{CF}_{3} \mathrm{SO}_{3}\right]_{2}$ or other similar homoleptic imidazole complexes, so the effect of the

Figure 6.13 Cell viability vs. concentration for $\left[\mathrm{Ru}\left(\mathrm{Me}_{2} \mathrm{biim}\right)_{3}\right]\left[\mathrm{CF}_{3} \mathrm{SO}_{3}\right]_{2}$ (27), with error bars representing $95 \%$ confidence limit.
bidentate versus the corresponding monodentate ligands cannot be compared. Previous work in our group showed that incubation of SCCVII cells with $\left[\mathrm{Ru}(\mathrm{Im})_{6}\right]\left[\mathrm{CF}_{3} \mathrm{SO}_{3}\right]_{2}$ for 3 h did lead to some Ru uptake into the cells. ${ }^{6}$ Further study of these $\mathrm{Ru}(\mathrm{II})$ systems is needed to arrive at a better understanding of their behaviour, and to determine what effect the biimidazoles produce with respect to complexes with monodentate imidazoles.

Figure 6.14 Cell viability vs. concentration for $\left[\mathrm{Ru}(\text { biim })_{3}\right]\left[\mathrm{CF}_{3} \mathrm{SO}_{3}\right]_{2}$ (26), with error bars representing 95\% confidence limit.

### 6.4.4 Ru Carboxylate complexes

A Ru (III) complex with imidazole-4-carboxylic acid (32), and a mixed valence $\mathrm{Ru}(I I / I I)$ bimetallic complex with picolinic acid (31) (Figure 6.15) were also tested using the MTT assay. Both exhibited higher $\mathrm{IC}_{50}$ values than did the imidazole maltolato complexes (Table 6.6); the $\mathrm{IC}_{50}$ value per Ru atom for the mixed valence species would be $200 \mu \mathrm{M}$. Further study of these two complexes is still warranted as they do show activity toward this cell line.

Figure 6.15 Cell viability vs. concentration for $\left[\mathrm{Ru}_{2}(\mathrm{pic})_{4}(\mathrm{EtOH}) \mathrm{Cl}\right] \cdot \mathrm{H}_{2} \mathrm{O}$ (31), with error bars representing $95 \%$ confidence limit.

### 6.5 Summary

Direct comparison of the MTT assay data obtained here with those from other groups is difficult as results likely vary depending on the cell line used. However, by comparison with data for cisplatin, it is clear that a number of the Ru complexes show significant antiproliferatory activity and should be studied further to determine how they behave inside the cell. $\mathrm{IC}_{50}$ values reported for other $\mathrm{Ru}(I I I)$ complexes, as determined by MTT assays, include those for NAMI (Section 1.5.3.2) against the human colon cancer cell lines SW707 (195 $\mu \mathrm{M}$ ) and SW948 ( $220 \mu \mathrm{M}$ ), ${ }^{3}$ and that reported for a complex written as $[\mathrm{H}]\left[\mathrm{Ru}(1,2\right.$-dimethylimidazole $\left.) \mathrm{Cl}_{4}\right]$ against $\mathrm{SKW}-3$ cells( $>400 \mu \mathrm{M}$ ), a human T-lymphoma cell line. ${ }^{4}$

Ideally, the best way to gauge the activity of the new Ru complexes would be to test them simultaneously with NAMI-A, which is currently undergoing phase I clinical trials (Section 1.5.3.2), or other standards on the same cell line, and compare their activities. Performing these tests on the same cell lines and at the same time under the
same conditions would lead to a more comprehensive understanding of the effectiveness of the various complexes, and perhaps of their different levels of activity in different tumour models. Performing MTT assays on other cell lines, particularly cisplatin resistant cell lines, would also help determine the effectiveness of these new Ru complexes to arrest cell proliferation.

## Chapter 7

## In Vitro Toxicity, Ru-Uptake and Ru-DNA Binding Studies of Ru Complexes, and Antibody Recognition Studies of a New Nitrotriazole in Chinese Hamster Ovarian (CHO) Cells

### 7.1 Introduction

A persistent problem in radiation therapy of cancerous tumours is that many tumours contain hypoxic regions that are resistant to radiation treatment. Rapid growth of tumours can lead to inadequate vasculature development and thus poor transport of oxygen to the tumour cells. ${ }^{1}$ Typically an oxygen-gradient will be established with the innermost part of tumour being lowest in oxygen concentration (see Chapter 1, Figure 1.1); these oxygen depleted regions in which the cells are still viable, are called hypoxic regions, and their resistance to many treatments makes it important to identify these regions before a treatment is prescribed. ${ }^{1}$

Nitroimidazoles have been shown to accumulate in hypoxic cells, the nitro group being reduced inside the cell and the resulting reduced species then reacting with macromolecules to form adducts. ${ }^{2}$ Quantification of the nitroimidazole content inside cells can help identify regions of hypoxia. ${ }^{1}$ Through incorporation of radioactive atoms into the nitroimidazole, the localization of the radioactive species can be quantified using SPECT, PET, or MRI imaging. ${ }^{1}$ Antigenic properties of the resulting adducts can also be used to quantify the levels of drug uptake by removing a tissue or cell sample and treating it with monoclonal antibodies. The concentration of bound antibodies can then be determined using fluorescence spectroscopy. ${ }^{3,4}$

There are literature examples of Ru complexes binding to DNA bases, ${ }^{5-7}$ but in order to propose a mechanism of action involving DNA binding (as with cisplatin), one must first determine if the complex is in fact reaching the DNA in vitro and binding to it. It has also been suggested that some Ru complexes may act through extracellular mechanisms. ${ }^{8}$ If so, then one would not expect to find correlation between the cellular uptake of Ru and the biological activity of the complex. The results of Ru-uptake and

DNA binding assays, discussed in this chapter, give information not only about hypoxia selectivity, but also about how and where the complexes might be interacting inside the cells. Furthermore, a lower plating efficiency of the cells after their incubation with a given complex for 3 h , an arbitrarily chosen time, compared with that of the control, indicates that the complex is having a cytotoxic or antiproliferatory effect on the cells over this period.

### 7.2 General Experimental

### 7.2.1 Materials, Media, and Prepared Solutions

Eagle's minimum essential medium powder ( $\alpha$-modification), and penicillin/streptomycin antibiotic were purchased from Gibco. Sterile tissue culture dishes ( 5 cm diameter), T-25 and T-75 flasks, and 15 and 50 mL Conical tubes were purchased from Falcon. Methylene blue was purchased from Aldrich. Other materials used in this chapter are listed in Section 6.2 .1 (p 132). The media were prepared by the staff in the biological services laboratory in the UBC chemistry department. $\alpha-/$ Medium was prepared by adding one packet of $\alpha$-medium powder and 10,000 units of penicillin/streptomycin antibiotic to 1 L of doubly distilled (dd) $\mathrm{H}_{2} \mathrm{O}$, and stirring the resulting solution for 2 h at r.t. $\alpha+/$ - Medium was prepared by adding $10 \%$ heatinactivated fetal bovine serum (FBS) to $\alpha-/-$ medium buffered with 10 mM HEPES. $\alpha+/+$ medium was prepared by adding $10 \% \mathrm{FBS}$ and $\mathrm{Na}\left(\mathrm{HCO}_{3}\right)(2 \mathrm{~g} / \mathrm{L})$ to $\alpha-/$ - medium and then adjusting the pH to 7.30 with 2 M NaOH . The media were then filter- sterilized and stored at $4^{\circ} \mathrm{C}$, while the trypsin-EDTA and FBS were stored at $-20^{\circ} \mathrm{C}$.

Methylene blue solution was prepared by dissolving the solid (Aldrich) ( 200 mg ) in 100 mL of $\mathrm{ddH}_{2} \mathrm{O}$; the resulting solution was filtered through a $0.1 \mu \mathrm{~m}$ filter to remove any undissolved solid and stored at $4{ }^{\circ} \mathrm{C}$.

The following solutions were prepared exclusively for the monoclonal antibody binding assay (Section 7.3.4) with the assistance of staff at the BC Cancer Research Centre (BCCRC): PBS* was prepared by adding $0.25 \%$ (v/v) 0.1 M Thimerosal (Aldrich) and $0.25 \%(\mathrm{v} / \mathrm{v}) 1.0 \mathrm{M} \mathrm{NaN}_{3}$ to the standard PBS solution. $\mathrm{PBS}^{\text {II }}$ was prepared by adding 0.3 \% Tween 20 (Aldrich) (v/v) to a PBS* solution. Ab Carrier, available
from BCCRC, consisted of $1.5 \%$ bovine serum albumin ( 0.15 g ) in $\mathrm{PBS}^{\mathrm{tt}}(10 \mathrm{~mL})$; as the bovine serum albumin is partially insoluble, the suspension was stirred at $37{ }^{\circ} \mathrm{C}$ for 1 h prior to use. Blocking solution was also available from BCCRC and consisted of $20 \%$ skim milk and $5 \%$ mouse serum added to the Ab Carrier mixture. Paraformaldehyde ( pF ) was prepared by boiling a solution of $100 \mu \mathrm{~L}$ of 1 M NaOH in $60 \mathrm{~mL} \mathrm{ddH} \mathrm{H}_{2} \mathrm{O}$, and then adding this to a slurry of 4 g pF in $30 \mathrm{~mL} \mathrm{ddH} \mathrm{H}_{2} \mathrm{O}$. The resulting colourless solution was cooled to $0^{\circ} \mathrm{C}$, when 10 mL of 10x PBS (available at BCCRC and having ten times the ionic strength of normal PBS) were added. This mixture was then filtered through a 0.22 $\mu \mathrm{m}$ sterile filter and to the filtrate was added $100 \mu \mathrm{~L}$ of 1 M HCl . pF was stored at $0^{\circ} \mathrm{C}$. The monoclonal antibody (MoAb), ELK3-51, was donated by Dr. C Koch (University of Pennsylvania) to BCCRC.

Atomic absorption spectroscopy (AAS) was performed by Celator Technologies on a Varian SpectrAA-300 Zeeman Atomic Absorption Spectrometer controlled by a Compaq Deskpro 386s computer. The instrument was calibrated using stock solutions of Ru from Aldrich, and a Ru hollow cathode lamp at a 10 mA current $\left(\lambda_{\max }=349.9\right.$ ). A reslope calibration was performed after every fifth sample to ensure that there was no significant shift in the background reference.

### 7.2.2 Cell Preparation

Chinese Hamster Ovarian (CHO) cells were donated by Dr. K. Skov at the BCCRC (Figure 7.1). After the cell culture was grown for three days, the cells were passaged and a frozen stock of cells was prepared (ten 1 mL vials containing $1 \times 10^{6}$ cells in medium with $5 \% \mathrm{DMSO}$ ). The cells were maintained in T-75 tissue culture flasks in a $5 \% \mathrm{CO}_{2}$ /air incubator from Forma Scientific in $\alpha+/+$ media at $37^{\circ} \mathrm{C}$. The cells were transferred every 3-4 days using the procedure described in Section 6.2.2 for the MDA-MB-435S cell line, but using $\alpha+/+$ medium instead of $\mathrm{L}-15$ medium.

Figure 7.1 CHO cells in $\alpha+/+$ medium $\left(\sim 10^{6}\right.$ cells $\left./ \mathrm{mL}\right)$.

### 7.2.3 Stock Solutions of Ru Complexes

The Ru complexes were weighed into glass vials and dissolved in PBS to a concentration of $1.0 \mathrm{mM} ; 3.0 \mathrm{~mL}$ of stock solution were prepared for each complex. These solutions were then sonicated and heated to $37{ }^{\circ} \mathrm{C}$ to ensure the complex was completely dissolved, and then filter-sterilized through $0.2 \mu \mathrm{~m}$ filters, to remove an remaining particulates.

### 7.3 Hypoxia Selectivity Assays

### 7.3.1 Incubation of Complexes and Plating Efficiency

The hypoxia assays were performed at UBC in an innova 4300 incubator shaker (from New Brunswick Scientific) under a flow of $\mathrm{N}_{2}$ or air, according to established protocols. ${ }^{9}$ Centrifugation was performed on a Dynac Centrifuge. $\alpha+/$ - medium ( 8 mL ) and Ru complex solution ( 1 mL ) were added to 50 mL Falcon tubes. In most cases, two tubes were prepared for each complex, one for incubation under air, the other under $\mathrm{N}_{2}$; however, some complex solutions were only tested under an air atmosphere (see Table 7.2, Section 7.4.2). The tubes were then placed in the incubator, attached to a gas line, shaken (150 rpm) at $37^{\circ} \mathrm{C}$ for 1 h (Figure 7.2), and then removed from the incubator and
placed in a sterile hood. To each tube was then added 1 mL of a prepared cell suspension containing $3 \times 10^{6}$ cells $/ \mathrm{mL}$ in $\alpha+/$ - medium. The tubes were then placed back in the incubator, reattached to the gas lines, and shaken ( 150 rpm ) at $37^{\circ} \mathrm{C}$ for 3 h . The suspensions were then transferred to 15 mL Falcon tubes and centrifuged ( 8 min at 800 $\mathrm{rpm})$. The supernatant was removed, and the cells were resuspended in 5 mL of PBS to rinse them of any remaining Ru. The cell suspensions were centrifuged again ( 8 min at $800 \mathrm{rpm})$ and the supernatant removed. The pellets were then resuspended in 2 mL of PBS and the cell density of each suspension was determined by counting the cells under a microscope using a hemacytometer. A $10 \mu \mathrm{~L}$ aliquot of each cell suspension was then added to 5 mL of $\alpha+/-$ medium and the mixture vortexed to ensure that the diluted cell suspensions were homogeneous; $50 \mu \mathrm{~L}$ of each of these was then added to 5 mL of $\alpha+/+$ medium in a 5 cm tissue culture dish. This was repeated 2 more times giving a total of 3 dishes for each sample. The tissue culture dishes were then placed in the $5 \% \mathrm{CO}_{2}$ incubator for 7 days to allow colonies to form.

Figure 7.2 Conical tube set-up used for CHO experiments (gas $=$ air or $\mathrm{N}_{2}$ ).

The remaining 2 mL suspension in PBS and 5 mL suspension in $\alpha+/$ - medium were combined for each sample and centrifuged ( 8 min at 800 rpm ). The cells in each flask were then resuspended in 2 mL of PBS. For those samples for which the DNA binding assay was performed, the suspensions were then divided in half, with 1 mL of the
cell suspension being used for the Ru-uptake assay (Section 7.3.2), and the other half for the DNA binding determination (Section 7.3.3). For those samples for which only the Ru-uptake assay was performed, the entire 2 mL suspension was used for the procedure. Alternately, for the Ru-free compounds, EF5 and triF5, only the monoclonal antibody binding assay was performed, the 2 mL suspension being used to carry out the procedure described in Section 7.3.4.

After 7 days, the medium was removed from each dish and methylene blue solution was added $(0.40 \mathrm{~mL})$. The dishes were swirled to ensure the dye covered the entire surface of the dish and, after 10 min , the dishes were rinsed with water and the remaining colonies (Figure 7.3) were counted to determine the plating efficiency (PE), defined as the number of colonies counted for each sample divided by the number of cells plated 7 days earlier.

Figure 7.3 Colony of CHO cells after 7 days, following staining with methylene blue.

### 7.3.2 Ru-Uptake Determination

The final cell suspensions allotted for Ru-uptake determination ( 1 or 2 mL , see Section 7.3.1) were transferred to a fresh 15 mL Falcon tube and then centrifuged ( 10 min at 800 rpm$)$. The supernatant was then removed and the tubes were placed with lids open in the shaker incubator ( $37^{\circ} \mathrm{C}, 150 \mathrm{rpm}$ ) for 16 h to dry the cell pellets. Conc. $\mathrm{HNO}_{3}(100 \mu \mathrm{~L})$ was then added to each tube, which was then closed and left at r.t. for 24
h in order that the cell pellet be digested. Then, $250 \mu \mathrm{~L}$ of $\mathrm{ddH}_{2} \mathrm{O}$ was added to dilute the acid, and the samples were then sent for AAS to determine the Ru content of each sample.

### 7.3.3 DNA Isolation

The DNA isolation was performed using a Wizard Genomic DNA Purification Kit from Promega. The 1 mL aliquots of the cell suspensions (see Section 7.3.1) were transferred to 1.5 mL microcentrifuge tubes and pelleted using centrifugation ( $15,000 \times g$ for 10 s ). The supernatant was then removed from each tube, leaving the cell pellet in $\sim 50 \mu \mathrm{~L}$ of residual medium. PBS $(200 \mu \mathrm{~L})$ was then added to each pellet, and these mixtures were vortexed at high speed for 30 s to resuspend the cells. The cell suspensions were then centrifuged again ( $15,000 \times g$ for 10 s ). The supernatant was again discarded from each tube leaving the cell pellets in approximately $20 \mu \mathrm{~L}$ of liquid. Nuclei Lysis Solution ( $600 \mu \mathrm{~L}$ ) (from the Kit) was then added to each cell pellet, and the mixtures gently "pipetted" until no visible clumps of cells remained. RNase ( $3 \mu \mathrm{~L}$ ) Solution (from the Kit) was then added to each tube, and the samples were mixed. The cell mixtures were then incubated for 30 min at $37^{\circ} \mathrm{C}$ to allow the cells to lyse. The tubes were then removed from the incubator and cooled to r.t. Protein Precipitation Solution $(200 \mu \mathrm{~L})$ (from the Kit) was then added to each tube, and the resulting mixtures were vortexed at high speed for 20 s and then cooled in an ice-bath for 5 min . The tubes were then centrifuged $(15,000 \times g$ for 4 min ) causing the precipitated protein to form a white pellet at the bottom of each tube. The supernatant containing the DNA was then carefully removed and transferred to a clean 1.5 mL microcentrifuge tube containing 600 $\mu \mathrm{L}$ of isopropanol. The resulting solutions were then carefully mixed by inverting the tubes until white, thread-like strands of DNA became visible. The tubes were then centrifuged ( $15,000 \times g$ for 1 min ) to pellet the DNA. The supernatant was then removed and $600 \mu \mathrm{~L}$ of $70 \%$ aq. EtOH was added. The tube was inverted several times to wash the DNA. The tubes were again centrifuged at $15,000 \times g$ for 1 min to pellet the DNA and the EtOH was aspirated with a pipette leaving only the DNA pellet. The tubes were then left open and inverted over a paper towel to air dry the pellet for 30 min . Finally, $100 \mu \mathrm{~L}$ of DNA Rehydration Solution (from the Kit) was added to each tube and the
sealed tubes were then heated at $65^{\circ} \mathrm{C}$ for 1 h . The tubes containing the rehydrated DNA were then stored at $4{ }^{\circ} \mathrm{C}$ until the amount of isolated DNA from each sample was determined by UV-Vis spectroscopy (Section 7.3.3.1) and the amount of associated Ru by AAS .

The amount of DNA in each sample was determined by measuring the optical density, and then employing Equation 7.1. The absorption of a DNA suspension was recorded at both 260 and 280 nm on a Perkin Elmer Lambda 2 UV/VIS spectrometer in a 1 cm optical cell. The ratio of the absorptions at 260 and 280 nm provides a check on the DNA purity: values $>1.7$ are considered to be good, ${ }^{10}$ and for all the samples, this ratio was between 1.71 and 1.85. The rehydrated DNA samples were diluted from 30 to 800 $\mu \mathrm{L}$, a dilution factor of 26.67 , before the absorbances at 260 and 280 nm were recorded.
$\mathrm{A}(\mathrm{OD}) \times \mathrm{D} \times 50\left(\mathrm{ng} \mathrm{mL} \mathrm{L}^{-1} \mathrm{OD}^{-1}\right) \times(0.100 \mathrm{~mL})=\mu \mathrm{g}$ DNA (Eq. 7.1)
$\mathrm{A}=$ absorption at $260 \mathrm{~nm}, \mathrm{D}=$ dilution factor, 0.100 mL is the total sample volume and 50 is a constant.

### 7.3.4 Monoclonal Antibody Binding Assay

This assay was performed at the BCCRC with the assistance of Haibo Zhou. The two compounds tested, EF5 and triF5, were incubated with CHO cells using the procedure described in Section 7.3.1 for the incubation of complexes. The 2 mL cell suspensions from the EF5 and triF5 experiments were then centrifuged ( 8 min at 800 rpm ) and the supernatant, removed from each using a $1000 \mu \mathrm{~L}$ micropipettor, was discarded. $\mathrm{pF}(3 \mathrm{~mL})$ was then added dropwise to each tube as it was vortexed at medium speed. The tubes were then inverted continuously for 1 h at $4^{\circ} \mathrm{C}$. After 1 h , the cells were centrifuged ( 8 min at 800 rpm ) and washed twice with PBS* (by addition of 5 mL of PBS*, centrifugation for 8 min at 800 rpm and then removal of the supernatant). After the second wash, the cells were resuspended in 1 mL PBS* and then transferred to Eppendorf tubes. These were then centrifuged ( 8 min at 800 rpm ), their supernatant removed, and $100 \mu \mathrm{~L}$ of blocking solution was added to each tube (blocking solution prevents the antibody from binding molecules other than the intended target inside the cell). The tubes were then inverted for 5 h at $4^{\circ} \mathrm{C}$. Then 1 mL of PBS* was added to each Eppendorf tube, and these were shaken gently to mix the suspensions. The mixtures
were then centrifuged ( 8 min at 1200 rpm ) and the supernatant removed; $100 \mu \mathrm{~L}$ of a MoAb solution was then added (the ELK3-51 antibody was conjugated to a Cy3 fluorescent label ${ }^{11}$ (Figure 7.4) to make detection of the antibody possible, and the MoAb solution contained a 20:1 mixture of Ab Carrier: MoAb ). The resulting suspensions were then covered with Al foil and rotated overnight at $4^{\circ} \mathrm{C}(12 \mathrm{~h})$. (Note: all work with the MoAb was done in a dark-room as the intensity of the fluorescence of the MoAb decreases if the antibody is exposed to light). The samples were then centrifuged ( 8 min

Figure 7.4 Structure of the fluorescent dye, Cy 3 , used to label the ELK3-51 MoAb.
at 1200 rpm ) and the supernatant containing the MoAb solution was removed. $\mathrm{PBS}^{\mathrm{tt}}$ was then added to each tube and the resulting mixtures gently vortexed to resuspend the pellet. The tubes were then rotated for 40 min at $4^{\circ} \mathrm{C}$, centrifuged ( 8 min at 1200 rpm ), and the supernatant discarded. This procedure was repeated two more times. After the last wash with $\mathrm{PBS}^{t t}$, the samples were resuspended in $400 \mu \mathrm{~L}$ of $\mathrm{PBS}^{t t}$. These suspensions were diluted with 2 mL of $1 \% \mathrm{pF}$ and then submitted for analysis at BCCRC by flow cytometry. The final suspensions were stored at $4{ }^{\circ} \mathrm{C}$ for $1-2$ weeks before the analyses were performed.

The concentration of MoAb adducts and thus the concentration of EF5 or triF5 in a given sample was measured by a technician at BCCRC on a Coulter Epics Elite fluorescence-activated cell-sorter, with a Coherent Inova 90 Ar laser. Detection of the MoAb adducts is facilitated by the Cy 3 label on the MoAb . The sample is passed through the laser using an ultrasonic vibrator to split the sample into droplets; only drops
containing a single cell were analyzed. The laser was set to 510 nm for the excitation wavelength, and the emission was detected between $580-590 \mathrm{~nm}$. For each sample, the fluorescence of 10,000 cells was measured.

### 7.4 Results and Discussion

### 7.4.1 Plating Efficiency of CHO Cells

The toxicity of several compounds (Table 7.1) was investigated under hypoxic (under $\mathrm{N}_{2}$ ) and oxic (under air) conditions by determining the plating efficiency (PE) of the cells after a 3 h incubation period in media usually containing $100 \mu \mathrm{M}$ of the compound; $\left[\mathrm{Ru}(\mathrm{ma})_{2}(\mathrm{EF} 5)_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3} \cdot \mathrm{EtOH}$ (14) was tested at $48 \mu \mathrm{M}$ because of a solubility limitation. The procedure for this experiment is outlined in Section 7.3.1. The plating efficiency was determined by counting the colonies for of the 3 replicates for each sample, and then dividing by the number of cells plated 7 days earlier after the 3 h incubation with the complex.

The PE data (Table 7.1) are the average of two experiments, each having a plating efficiency determined by averaging the number of colonies in the 3 replicates. For the controls, the values are the average of six experiments, as a control was performed each time a complex or ligand was tested, and only 5 complexes could be tested at once. The error in the PE of the controls is only $\pm 4 \%$ because there are more experiments within the average value, and the variation of the PE values for the controls was less than those for the complexes. Several of the complexes do exhibit a small cytotoxic effect; however, there is no significant hypoxia selectivity observed for the PE of any of the complexes. The two nitro-heterocycles, EF5 and triF5, showed no toxicity at all. Repeating these experiments might be valuable as a greater number of trials would decrease the error limits. The experiments could also be lengthened or monitored over time to determine how the amount of complex in the cells varies with time. The use of a Coulter counter (not available in the UBC chemistry department) might help reduce the errors as counting cells on the hemacytometer was not very accurate for this particular assay. Clumping of cells was a major problem, both in the counting of cells, and the fact
that cell clumps form large cell masses (Figure 7.5) and not individual countable colonies.

Figure 7.5 Large cell colony formations resulting from clumped cells (A and B) compared with a colony grown from a single cell over the same time period, C.

Our group has previously synthesized and tested similar Ru-acac-imidazole and -nitroimidazole complexes in SCCVII cells, and also found no hypoxia selective toxicity. ${ }^{12}$

There may be several reasons why the PEs of complexes active in the MTT assay (with $\mathrm{IC}_{50}$ values well below $100 \mu \mathrm{M}$, see Section 6.4) do not show any significant toxicity in this PE assay. A different cell line was used here than that for the MTT assay (CHO vs. MDA-MB-435S) because of past experience at BCCRC in which CHO cells were known to provide a good model for testing hypoxia. This PE assay also differs in that the incubation is only 3 h compared with 69 h for the MTT assay, and the complexes may not accumulate quickly enough to have a significant effect on the cells. The cells are also plated in media in which no complex is present. If the complexes are able to diffuse out through the cell membrane, then an equilibrium between complex inside and outside the cell may be important; removing the extracellular complex may drive the complex outside of the cell. This sort of mechanism is not unreasonable, as there is no evidence to suggest that the complex decomposes inside the cell, and no intracellular targets have yet been established to suggest that, once the complex is taken up, it is 'trapped' inside the cell.

Table 7.1 Plating efficiency ${ }^{a}$ of CHO cells after a 3 h incubation period under both aerobic and anaerobic conditions with several Ru (III) complexes at 100 $\mu \mathrm{M}$.

| Compound | PE-oxic | PE-hypoxic |
| :---: | :---: | :---: |
| Control | $69^{\text {b }}$ | $66^{6}$ |
| $\mathrm{Ru}(\mathrm{ma})_{3}(\mathbf{1})$ | 42 | 35 |

### 7.4.2 Ru-Uptake

The uptake of Ru into CHO cells was determined in order to help understand how the $\mathrm{Ru}(\mathrm{III})$ complexes that showed low $\mathrm{IC}_{50}$ values (Chapter 6) might be acting in vitro. Sava and Bergamo ${ }^{8}$ have suggested that some Ru complexes may bind extracellular components in order to produce cytotoxic or antiproliferatory effects, while others may act with intracellular components such as proteins or DNA to produce a biological effect. In the former case, one would expect low levels of Ru to be taken up into the cells. In the latter case, the level of activity might be dependent on the amount of complex in the cell.

The data (Table 7.2) show that the complexes containing the Ema ligands (2, 12 and 13) are taken up more readily into the cells than the corresponding ma complexes ( $\mathbf{1}$, 6, and 10), and the former group also exhibit lower $\mathrm{IC}_{50}$ values in MDA-MB-435S cells than the latter group (Section 6.4.2). This suggests a link between the Ru-uptake and antiproliferatory activity for these complexes. Conversely, the Ru-uptake for $\left[\mathrm{Ru}(\mathrm{ma})_{2}(2 \mathrm{MeIm})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$ (10) and $\left[\mathrm{Ru}(\mathrm{ma})_{2}(1 \mathrm{MeIm})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3} \cdot \mathrm{CH}_{2} \mathrm{Cl}_{2}$ (8) under both oxic and hypoxic conditions are exactly the same for each complex, whereas the corresponding $\mathrm{IC}_{50}$ values are 5 and $70 \mu \mathrm{M}$, respectively (Section 6.4.2). These findings imply that the nature of the imidazole ligand is important for the biological effect; as the free imidazoles ( 2 MeIm and 1 MeIm ) alone produce no significant cytotoxic effect (Section 6.4.1), at least one of the imidazole ligands must remain bound in vitro in order for the Ru complexes to produce their biological effects.

CHO cells incubated with $\left[\mathrm{Ru}(\mathrm{ma})_{2}(\mathrm{EF} 5)_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3} \cdot \mathrm{EtOH}(14)$ showed the highest level of Ru-uptake, suggesting that this complex is taken up more readily than analogous imidazole- and nitroimidazole-maltolato complexes; $\mathbf{1 4}$, however, exhibits no significant antiproliferatory activity (Section 6.4.2), nor does this complex accumulate selectively in hypoxic cells as does free EF5 (Section 7.4.4). Indeed, none of the complexes tested under both oxic and hypoxic conditions shows any hypoxia selectivity (Table 7.2). The Ru-uptake values reported for 14 (Table 7.2) are for a 3 h incubation at $48 \mu \mathrm{M}$ as determined by AAS after the complex solution had been filtered. Other workers have noted a linear correlation between Ru-uptake vs. concentration at concentrations below $100 \mu \mathrm{M}$ in MEM (minimum essential medium), ${ }^{13}$ suggesting that at $100 \mu \mathrm{M}$, the values listed in Table 7.2 for 14 would be 169 and $152 \mathrm{ng} \mathrm{Ru} / 10^{6}$. cells under oxic and hypoxic conditions, respectively.

For the biimidazole complexes, the Ru-uptake values for $\left[\mathrm{Ru}(\mathrm{ma})_{2}(\mathrm{biim})\right] \mathrm{CF}_{3} \mathrm{SO}_{3} \cdot 2 \mathrm{H}_{2} \mathrm{O}$ (24) and $\left[\mathrm{Ru}(\mathrm{ma})_{2}\right.$ (Mebiim) $] \mathrm{CF}_{3} \mathrm{SO}_{3} \cdot 2 \mathrm{H}_{2} \mathrm{O}$ (25) are very similar, as are the values for $\left[\mathrm{Ru}(\mathrm{biim})_{3}\right]\left[\mathrm{CF}_{3} \mathrm{SO}_{3}\right]_{2}$ (26) and $\left[\mathrm{Ru}(\mathrm{Mebiim})_{3}\right]\left[\mathrm{CF}_{3} \mathrm{SO}_{3}\right]_{2}$ (27). Nevertheless, the complexes with perhaps higher uptake ( $\mathbf{2 5}$ and 26) do have lower $\mathrm{IC}_{50}$ values ( 15 and $10 \mu \mathrm{M}$, respectively) than do 24 and 27 ( 50 and $25 \mu \mathrm{M}$, respectively). Further experiments that might help determine if these differences are real or not will be noted in Chapter 8.

[^5]Recently, Frausin et al. have examined the Ru-uptake of NAMI-A in KB cells (human nasopharynx cancer cells), and concluded that the complex enters the cell both by passive diffusion across the membrane and by active transport. ${ }^{14}$ Over $4 h$, at both 4 and $37{ }^{\circ} \mathrm{C}$, the complex only accumulated in the cells at the higher temperature, the Ru-uptake increasing when the experiment was performed in PBS instead of MEM; this was thought
to result from competition for transport sites in the membrane with other components present in MEM. When the concentration was varied between 10 and $1000 \mu \mathrm{M}$, the percent of Ru taken into the cell remained constant in MEM, while in PBS, the percent of Ru-uptake from the total present in solution decreased as the concentration increased. ${ }^{14}$

Ru-uptake data have also been reported for the dimeric Ru complexes $\left[\mathrm{RuCl}_{4}(\mathrm{DMSO})\right]_{2}(\mu-\mathrm{L})$, where $\mathrm{L}=$ pyrazine, pyrimidine, 4,4 -bipyridine as well as other substituted pyridine ligands; ${ }^{13}$ these were also tested against KB cells, and uptake values were similar to those found for NAMI-A in the same cell.

Further experiments examining the Ru-uptake of the complexes discussed in this section might help to understand how the complexes act in vitro. Use of the MDA-MB435 S cell line used for the MTT assay (Chapter 6) instead of CHO cells would allow a more direct comparison to be made between the Ru-uptake values (Table 7.2) and $\mathrm{IC}_{50}$ values (Section 6.4.1, Table 6.6).

### 7.4.3 Ru-DNA Binding

DNA was isolated from cells after a 3 h incubation with a selected $\mathrm{Ru}(I I I)$ complex in order to determine if it was interacting with DNA. With the exception of $\left[\mathrm{Ru}(\mathrm{ma})_{2}(\mathrm{EF} 5)_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3} \cdot \mathrm{EtOH}(\mathbf{1 4})$, none of the other complexes tested (1, 2, 4, 6, 8, 10) exhibited any DNA binding (Table 7.3). 14 exhibits some hypoxia selectivity for binding DNA: 5.9 and $10.5 \mathrm{ng} \mathrm{Ru} / \mathrm{mg}$ DNA at $48 \mu \mathrm{M}$ for oxic and hypoxic conditions, respectively. Previous studies in our group with $\left[\mathrm{Ru}(\mathrm{acac})_{2}(\mathrm{EF} 5)_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$ in SCCVII cells ${ }^{12}$ showed that, after a 3 h incubation, the amount of bound Ru was 9.6 and 11.1 ng $\mathrm{Ru} / \mathrm{mg}$ DNA for oxic and hypoxic conditions, respectively. These values are calculated here for $48 \mu \mathrm{M}$ complex solutions, assuming that there is a linear correlation between Ru DNA binding and Ru concentration, as poor solubility of $\left[\mathrm{Ru}(\mathrm{acac})_{2}(\mathrm{EF} 5)_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$ limited its testing to a concentration of $22 \mu \mathrm{M} .{ }^{12}$ Such an assumption has been made for the Ru-uptake of NAMI-A at low concentrations. ${ }^{13}$ This complex also exhibited a 4-fold increase in fluorescence over that of free EF5 in the MoAb assay, ${ }^{12}$ suggesting that the complex facilitates the accumulation of EF5 inside the cell to a greater concentration

Table 7.3 Amount of $\mathrm{Ru}^{\mathrm{a}}$ associated with DNA isolated from CHO cells after a 3 h incubation period under both aerobic and anaerobic conditions with several $\mathrm{Ru}(\mathrm{m})$ complexes at $100 \mu \mathrm{M}$.

| Compound | Oxic $\begin{gathered} \mathrm{Ru}(\mathrm{ng} / \mathrm{mg} \text { DNA }) \\ ( \pm 3 \mathrm{ng} / \mathrm{mg}) \end{gathered}$ | $\begin{gathered} \text { Hypoxic } \\ \mathrm{Ru}(\mathrm{ng} / \mathrm{mg} \text { DNA) } \\ ( \pm 3 \mathrm{ng} / \mathrm{mg}) \end{gathered}$ |
| :---: | :---: | :---: |
| Control | 0 | 0 |

|  |  |  |
| ${ }^{\text {a }}$ Error limits are $\pm 3 \mathrm{ng} /$ <br> b The final concentration | limit $\sim 1 \mathrm{ng} / \mathrm{mg}$ D due to poor solub |  |

than when EF5 acts alone. The higher level of Ru-DNA binding for $\left[\mathrm{Ru}(\mathrm{acac})_{2}(\mathrm{EF} 5)_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$ suggests that, in the cell, the EF5 is being released from the complex and replaced by donor ligands of DNA. The same may be true for $\mathbf{1 4}$, and thus further study, in particular the MoAb binding assay, is needed on this complex. The DNA binding assay should also be repeated using the MDA-MB-435S cell line so that a more accurate correlation can be made between the DNA-binding results and the $\mathrm{IC}_{50}$ values from the MTT assay (Chapter 6).

For the other complexes, their method of action inside the cell does not include DNA binding; thus further experiments are needed to locate other potential targets for these complexes in vitro. In Section 7.4.5, a preliminary study will be discussed with Lcysteine potential intracellular target.

### 7.4.4 The Monoclonal Antibody Binding Assay

This assay was performed using only EF5 (Section 3.6.2) and the corresponding fluorinated nitrotriazole derivative, triF5 (Section 3.6.3). For triF5, detection of the MoAb adducts was carried out using flow cytometry and, as in the case of earlier work on EF5, ${ }^{12}$ triF5 accumulates preferentially in hypoxic cells (Figure 7.4). However, the mean fluorescence for the triF5 MoAb adducts was considerably less than that observed
for the EF5 MoAb adducts: at $100 \mu \mathrm{M}$, the signal for EF5 adducts are up to 7 times greater than that for triF5 adducts. More important is that the ratio of the hypoxic:oxic signals for triF5 is much less than that of EF5; in a search for new hypoxia imaging agents, this ratio determines the effectiveness of the compound to detect specifically hypoxic cells with low levels of background fluorescence in normal tissue.

Figure 7.6 Median fluorescence intensity of CHO cells incubated with EF5 or triF5 under $\mathrm{N}_{2}$ or air and then treated with the ELK3-51/Cy3 antibody.

### 7.4.5 Reaction of $\left[\mathrm{Ru}(\mathrm{ma})_{2}(2 \mathrm{MeIm})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}(10)$ with L-cysteine

An in situ, r.t. reaction of $\left[\mathrm{Ru}(\mathrm{ma})_{2}(2 \mathrm{MeIm})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}\left(\mathbf{1 0}\right.$, Section 3.7.9) in $\mathrm{D}_{2} \mathrm{O}$ $\left(\sim 10^{-3} \mathrm{M}\right)$ under air with 1 equivalent of L-cysteine (Figure 7.7) was followed by ${ }^{1} \mathrm{H}$ NMR spectroscopy. After 24 h , the initial intensities of the proton resonances for $\mathbf{1 0}$ were unchanged, and there were no new paramagnetic or diamagnetic signals, showing that $\mathbf{1 0}$ was still intact. The resonances for L-cysteine ( $\left.\delta 3.92(-\mathrm{CH}-), 3.08\left(-\mathrm{CH}_{2}-\right)\right)$ had decreased in intensity by $\sim 50 \%$, and new resonances for L-cystine ( $\delta 4.13$ (-CH-), 3.32
$\left.\left(-\mathrm{CH}_{2}-\right)\right)$ were present in about equal intensity as those for L-cysteine. In a control with only L-cysteine in $\mathrm{D}_{2} \mathrm{O}$, only trace amounts of L-cystine were present after 24 h .10 is apparently catalyzing the aerial solution oxidation of L-cysteine.

Figure 7.7 Molecular structure of L-cysteine

The ${ }^{1} \mathrm{H}$ NMR spectrum 10 in $\mathrm{D}_{2} \mathrm{O}$ in air remained unchanged for up to 48 h . For the L-cysteine sample at this time, the resonances for L-cystine were more intense than at 24 h , but still only $\sim 10 \%$ of the L-cysteine had been oxidized. In the spectrum of the 1:1, 10:L-cysteine system, there were no longer any resonances for L-cysteine present; and the only paramagnetic signals observed were those for $\mathbf{1 0}$, although a trace of 2 methylimidazole was now present in solution. No signals could be seen for either free or diamagnetically bound maltolato, showing that none of the initial $\mathrm{Ru}(\mathrm{II})$ had been reduced to $\mathrm{Ru}(I I)$. At the concentrations used, the signals for $\mathbf{1 0}$ are weak and difficult to resolve (minimum 150 scans, Section 3.3.2) and it is possible that trace amounts of other $\mathrm{Ru}(\mathrm{II})$ species might be present. The integration of the 2 -methylimidazole signals with respect to those of L-cystine suggests that $\sim 0.05$ equivalents of 2-methylimdiazole have dissociated, leaving $95 \%$ of intact $\mathbf{1 0}$. From this it can be concluded that the complex is catalytically oxidizing the cysteine to cystine in air. Repeating the reaction under Ar could give evidence for a reduced species.

TLC analysis after 48 h of solutions of $\mathbf{1 0}$, and $\mathbf{1 0}$ with L-cysteine, revealed the same band as a sample of $\mathbf{1 0}$ which had just been dissolved. All three samples also gave a brown spot $\left(R_{f}=0\right)$ that was less intense for the freshly prepared sample. No new bands for reduced species or newly formed complexes were observed.

Glutathione (a tripeptide containing a cysteine) can reduce certain $\mathrm{Ru}(I I I)$ species in situ, ${ }^{15}$ while reaction with glutathione is also the primary means by which cisplatin is deactivated in vivo. ${ }^{16}$ The stability of $\mathbf{1 0}$ in the presence of L-cysteine suggests that this complex is not being reduced in situ to a biologically active $\mathrm{Ru}(I I)$ species, and an intact or only partially substituted Ru (III) species is likely responsible for the antiproliferatory activity observed and not a species from which both imidazole ligands have been dissociated.

Further experiments monitoring the reaction of glutathione with $\mathbf{1 0}$ and other $\mathrm{Ru}(I I)$ complexes listed in Table 7.2 are needed to help determine more definitively the fate of the complex inside cells.

## Chapter 8

## Conclusions, and Direction of Future Work

### 8.1 Conclusions

Several new $\mathrm{Ru}(I I I)$-ma imidazole and -ma nitroimidazole complexes have been synthesized and tested for biological activity; selected, corresponding Ema complexes were also synthesized and tested (Chapter 3). The ${ }^{1} \mathrm{H}$ NMR spectra of the paramagnetic $\mathrm{Ru}(I I I)$-ma imidazole complexes were used to determine their purity and molecular structure. In the ${ }^{1} \mathrm{H}$ NMR spectra of 6,8 and 10 , single resonances for the ma-Me protons were assigned to the trans-ma, trans-imidazole isomer, and X-ray crystallography confirmed such a structure for $\mathbf{8}$ and 10. Similarly, in the ${ }^{1} H$ NMR spectra of the Ema complexes $11 \mathbf{- 1 3}$, single resonances for the $-\mathrm{CH}_{2}$ - groups were also assigned to transisomers, which was demonstrated for 11 by X-ray analysis. $\mathrm{Ru}(\amalg)$-ma complexes of nitroimidazoles in which the $\mathrm{N}(1)$ proton was not substituted (EF5 and metro are both 1substituted nitroimidazoles) were not soluble (without decomposition) in any solvent tested and were not obtained in high purity.

Ema complexes were taken up more readily into CHO cells than their ma analogues (Chapter 7), and this higher uptake corresponded with lower observed $\mathrm{IC}_{50}$ values (Chapter 6). Within the series of Ru-ma complexes, $\left[\mathrm{Ru}(\mathrm{ma})_{2}(2 \mathrm{MeIm})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$ (10) exhibited the lowest $\mathrm{IC}_{50}$ value ( $5 \mu \mathrm{M}$ ), while the corresponding Ema complex, $\left[\mathrm{Ru}(\mathrm{Ema})_{2}(2 \mathrm{MeIm})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}(13)$, exhibited the lowest $\mathrm{IC}_{50}$ value of all complexes tested, 500 nM . Differences in $\mathrm{IC}_{50}$ values that resulted from changes in the imidazole ligand did not correlate with changes in Ru-uptake. $\left[\mathrm{Ru}(\mathrm{ma})_{2}(\mathrm{EF} 5)_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3} \cdot \mathrm{EtOH}(14)$ exhibited the highest Ru-uptake of all the complexes tested (Chapter 7), and was the only complex to exhibit DNA binding, which increased by $\sim 50 \%$ under hypoxic conditions. Despite its high uptake and DNA binding values, this complex did not exhibit any noticeable antiproliferatory activity up to a concentration of $500 \mu \mathrm{M}$ (Chapter 6).

Of several new complexes synthesized using 4,4'-biimidazole ligands (Chapter 4), four $\mathrm{Ru}(\mathrm{II})$ and two Ru (III) species exhibited low $\mathrm{IC}_{50}$ values and warrant further investigation (Chapter 6). The biimidazole complexes vary in charge, oxidation state, and ancillary ligands, making it unclear what biological mechanism is operating, although more than one mechanism is likely involved judging by the similar activity of the different complexes. The findings suggest that known Ru complexes of other bidentate N -donor ligands such as $2,2^{\prime}$-bipyridine or $2,2^{\prime}$-biimidazole might also exhibit similar activity.

A triazole derivative of EF5 (triF5) was developed and tested for hypoxic selectivity, but was less specific for hypoxia than EF5; triF5 may utilize different metabolic pathways than EF5 or may be less able to bind the fluorescent antibodies used for detection.

Finally, some new Ru carboxylate complexes were synthesized and tested for biological activity (Chapter 5). In particular, a new bimetallic complex with picolinate (31) and a monomeric complex with $\operatorname{Im}-\mathrm{CO}_{2} \mathrm{H}$ (33) were studied. Preliminary reactions with a 3-nitro-1,2,4-triazole-5-carboxylic acid were also performed.

### 8.2 New Complexes to Synthesize and Test

$\mathrm{Ru}(I I I)$-ma complexes with nitroimidazole and nitrotriazole ligands containing an $\mathrm{N}(1)$-H group were not soluble in any solvent except DMSO in which they decomposed. Methylation at the $\mathrm{N}(1)$ position of $2 \mathrm{NO}_{2} \mathrm{Im}, 4 \mathrm{NO}_{2} \mathrm{Im}$ or $3 \mathrm{NO}_{2}$ tri might provide ligands that form stable Ru-ma complexes with higher solubilities, allowing for easier characterization and biological testing.

The high activity (low $\mathrm{IC}_{50}$ values) of several of the complexes containing biim and $\mathrm{Me}_{2}$ biim suggests that they should be studied in greater detail. Similar complexes with other N -donor ligands are known, but have not been tested for antiproliferatory activity or other biological activity. In particular, $\left[\mathrm{Ru}\left(2,2^{\prime} \text {-biimidazole }\right)_{3}\right]\left[\mathrm{PF}_{6}\right],{ }^{1,2}$ $\left.[\mathrm{Ru} \text { (imidazole) })_{6}\right]\left[\mathrm{CF}_{3} \mathrm{SO}_{3}\right]_{2}{ }^{3}$ and $\left[\mathrm{Ru}\left(2,2^{\prime} \text {-bipyridine }\right)_{3}\right]\left[\mathrm{PF}_{6}\right]_{2}{ }^{1,2}$ could be tested alongside $\left[\mathrm{Ru}(4,4 \text { '-biimidazole })_{3}\right]\left[\mathrm{CF}_{3} \mathrm{SO}_{3}\right]_{2}$ (26) to determine the effect of (a) changing from a monodentate imidazole to a chelating biimidazole, (b) changing the connectivity of the
biimidazole, and (c) changing the ring structure from imidazole to pyridine. Results from such comparisons could then give insight into the effect of the imidazole group, and could lead to new complexes with maltolato and other ancillary ligands (e.g. $\left[\mathrm{Ru}(\mathrm{ma})_{2}\left(2,2^{\prime}\right.\right.$-biimidazole $\left.\left.)\right] \mathrm{CF}_{3} \mathrm{SO}_{3}\right)$.

As noted in Chapter 7, complexes of Ema tend to be taken up more readily into cells than the corresponding ma complexes, and so the synthesis of the Ema derivative of $\left[\mathrm{Ru}(\mathrm{ma})_{2}(\mathrm{EF} 5)_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3} \cdot \mathrm{EtOH}(14)$ might lead to improved uptake in cells and higher levels of DNA binding.

New ma-complexes could be synthesized using some of the carboxylate ligands discussed (Chapter 5), for example, $\left[\mathrm{Ru}(\mathrm{ma})_{2}(\mathrm{HCANT})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$ or $\mathrm{Ru}(\mathrm{ma})_{2}(\mathrm{CANT})$ containing nitro-N-heterocycles. Similar-type complexes may also be possible with Hpic and $\mathrm{Im}-\mathrm{CO}_{2} \mathrm{H}$ ligands. The incorporation of the nitro and carboxylate groups within the N -heterocyclic ligand may significantly affect the biological properties.

Isopropylmaltol and $n$-butylmaltol are $\mathrm{known}^{4}$ and the corresponding tris(maltolato)complexes with Ru could be prepared and tested. Pyridinones, in which the O in the ma ring has been substituted by a N-R group, might also be useful ligands to try. A member of our group has synthesized $\mathrm{Ru}\left(3\right.$-hydroxy-1,2-dimethyl-4-pyronate) ${ }_{3}$, although attempts to incorporate some ancillary imidazole ligands has yet to yield positive results. ${ }^{5}$

### 8.3 New Directions for Hypoxia Markers

The high level of cellular uptake and selective DNA binding of $\left[\mathrm{Ru}(\mathrm{ma})_{2}(\mathrm{EF} 5)_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3} \cdot \mathrm{EtOH}$ (14) suggest that this complex is worth further investigation as a hypoxic marker. Previously in our group, Baird reported on the activity of $\left[\mathrm{Ru}(\mathrm{acac})_{2}(\mathrm{EF} 5)_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$ that showed a degree of Ru uptake into SCCVII cells similar to that found for 14 in CHO cells, but exhibited no selectivity toward hypoxic cells in the DNA binding assay. ${ }^{6}$ This complex did, however, show a 75 -fold increase in fluorescence in hypoxic cells over that observed in normal cells in the monoclonal antibody binding assay, and levels of fluorescence that were 4 times greater than those
for the free ligand alone (free EF5 itself also showed a 75 -fold selectivity for hypoxic cells). ${ }^{6}$ From these results it can be inferred that $\left[\mathrm{Ru}(\mathrm{acac})_{2}(\mathrm{EF} 5)_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$ is taken up by all cells equally, and once inside the cell the EF5 is released; the EF5 is then able to diffuse back out of the normal cells. This would account for the non-specific DNA binding and cellular uptake values for Ru , and the selective accumulation for EF5 in hypoxic cells. The complex may be taken up by cells more readily than the free ligand, thus resulting in the 4 -fold increase in fluorescence. Further tests with $\left[\mathrm{Ru}(\mathrm{acac})_{2}(\mathrm{EF} 5)_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$ were not pursued because of its poor water-solubility. $\left[\mathrm{Ru}(\mathrm{ma})_{2}(\mathrm{EF} 5)_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3} \cdot \mathrm{EtOH}(14)$ is more water-soluble than the acac analogue and, unlike $\left[\mathrm{Ru}(\mathrm{acac})_{2}(\mathrm{EF} 5)_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}$, shows selectivity for DNA binding in hypoxic cells. Results from the antibody binding assay with $\mathbf{1 4}$ might show that it is a viable candidate for further testing as a hypoxia imaging agent. The ELK3-51 antibody used to quantify EF5 was supplied by BCCRC; however, to continue this work, a new source for this antibody is needed.

### 8.4 Future Biotests

The higher cellular uptake of Ema complexes may mean that they can more readily diffuse across cell membranes. Lipophilicity studies would help determine if the complexes are entering the cell through passive diffusion or via an activated transport mechanism. The synthesis of complexes with isopropyl and n-butyl derivatives of ma would be useful in determining the effect of the ma-substituents on cellular uptake.

The Ru-uptake and Ru-DNA binding assays should be repeated using MDA-MB435 S cells. The CHO cells were used to mimic a hypoxic environment, but as only $\mathbf{1 4}$ exhibited any hypoxia selectivity, the other complexes should be tested on the same cell line used for the MTT assay in order to make more accurate correlations between cell uptake and antiproliferatory activity. In addition, complexes could be tested against other cancer cell lines to see if the activity is specific for the MDA-MB-435S cell line or if the effect of the complexes is more general. In particular, tumour cell lines resistant to cisplatin should be used to determine if these Ru-ma complexes are active against such tumour models in vitro.

As only 14 interacted with DNA in vitro, other tests are needed to determine what type of interaction the complexes experience inside the cell and how the complexes enter the cell. The latter can be tested by performing the Ru-uptake assay (see Section 7.3.2) using PBS in place of growth medium. For some other Ru complexes, ${ }^{7}$ the uptake of Ru has been found higher in PBS because components in the growth medium compete with the complex for active transport sites. In PBS, this competition for transport proteins is removed and the concentration of complex inside the cell increases. No increase in Ruuptake in PBS might suggest that the complex is entering the cell via passive diffusion.

To determine the ultimate fate of the complexes inside the cell, it would be helpful to first run a gel on a protein extraction from control MDA-MB-435S cells, and then on a protein extraction of cells that have been incubated with $\left[\mathrm{Ru}(\mathrm{Ema})_{2}(2 \mathrm{MeIm})_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3}\left(13\right.$, lowest $\mathrm{IC}_{50}$ value, Section 6.4.2). Differences in the protein expression between the two extractions may indicate how and where inside the cell the complex is interacting. Proteins that are either over- or under-expressed in the cells incubated with $\mathbf{1 3}$ could then be isolated from the gel, and identified by comparison of their amino acid composition with on-line library data. Gradient centrifugation could then be used to separate and isolate various components of the cell in which the identified proteins are known to be present.

Another experiment that could be performed to determine the cellular distribution of Ru is a micro-SRIXE study (Synchrotron Radiation-Induced X-ray Emission). This experiment can be used to detect the cellular distribution of elements, down to ppm levels. ${ }^{8}$ This technique has not been reported for detecting Ru , but has been employed to detect $\mathrm{Pt}, \mathrm{Zn}, \mathrm{K}, \mathrm{Cu}$, and Ca distributions inside cells. ${ }^{8,9}$

| Empirical formula | C22 H24 Cl2 F3 N4 O9 Ru S |
| :---: | :---: |
| Formula weight | 749.48 |
| Temperature | 173(2) K |
| Wavelength | 0.71069 A |
| Crystal system, space group | triclinic, $\quad$ P1 (\#2) |
| Unit cell dimensions | $\begin{array}{rlrl} \mathrm{a} & =9.1784(8) \mathrm{A} & \text { alpha }=64.082(14) \mathrm{deg} . \\ \mathrm{b} & =12.9918(3) \mathrm{A} & \text { beta }=78.771(19) \mathrm{deg} . \\ \mathrm{c}=13.6855(3) \mathrm{A} & \text { gamma }=85.95(2) \mathrm{deg} . \end{array}$ |
| Volume | 1439.48(13) $\mathrm{A}^{\wedge} 3$ |
| Z, Calculated density | 2. $1.729 \mathrm{Mg} / \mathrm{m} \wedge 3$ |
| Absorption coefficient | 0.878 mm ^-1 |
| F(000) | 754 |
| Crystal size | $0.20 \times 0.10 \times 0.02 \mathrm{~mm}$ |
| Theta range for data collection | 2.26 to 27.09 deg . |
| Index ranges | $-11<=h<=11,-16<=\mathrm{k}<=15,-17<=1<=16$ |
| Reflections collected / unique | $5707 / 5707$ [R(int) $=0.0000]$ |
| Completeness to 2 theta $=27.09$ | 90.18 |
| Refinement method | Full-matrix least-squares on $\mathrm{F}^{\wedge} 2$ |
| Data / restraints / parameters | $5707 / 69 / 421$ |
| Goodness-of-fit on $\mathrm{F}^{\wedge} 2$ | 0.981 |
| Final R indices [I>2sigma(I)] | $\mathrm{R} 1=0.0595, \mathrm{wR} 2=0.1345$ |
| $R$ indices (all data) | $\mathrm{R} 1=0.1147, \mathrm{wR} 2=0.1563$ |
| Largest diff. peak and hole | 1.049 and -0.802 e. $\mathrm{A}^{\wedge}-3$ |

## Appendix A3

## Experimental Details for the X-ray Crystallographic Study of trans$\left[\mathrm{Ru}(\mathrm{ma})_{\mathbf{2}} \mathbf{( 2 M e I m}_{2}\right]_{\mathrm{CF}_{3} \mathrm{SO}_{3}(\mathbf{1 0})}$

| Empirical formula | C21 H22 F3 N4 O9 S Ru |
| :---: | :---: |
| Formula weight | 664.55 |
| Temperature | 173.2 K |
| Wavelength | 0.7107 A |
| Crystal system, space group | Triclinic, $\mathrm{P}-1$ |
| Unit cell dimensions | $\begin{array}{rlrl} \mathrm{a} & =8.9512(6) \mathrm{A} & \text { alpha } & =94.908(5) \\ \mathrm{b} & =9.2949(7) \mathrm{deg} . \\ \mathrm{c} & =15.817(1) \mathrm{A} & \text { beta } & =93.453(5) \mathrm{deg} . \\ \text { gamma } & =93.059(4) & \text { deg. } \end{array}$ |
| Volume | 1306.5(2) A^3 |
| Z, Calculated density | 2, $1.689 \mathrm{Mg} / \mathrm{m}^{\wedge} 3$ |
| Absorption coefficient | 0.758 mm -1 |
| F(000) | 670.00 |
| Crystal size | $0.20 \times 0.15 \times 0.15 \mathrm{~mm}$ |
| Theta range for data collection | 2.20 to 27.86 deg . |
| Limiting indices | $-9<=h<=11, \quad-11<=k<=11, \quad-18<=1<=19$ |
| Reflections collected / unique | $11677 / 5269$ [R(int) $=0.04146]$ |
| Absorption correction | Semi-empirical from equivalents |
| Max. and min. transmission | 1.000 and 0.8142 |
| Refinement method | Full-matrix least-squares on $\mathrm{F}^{\wedge} 2$ |
| Data / restraints / parameters | 5269 / 0 / 363 |
| Goodness-of-fit on $\mathrm{F}^{\wedge} 2$ | 0.951 |
| Final R indices [I>2sigma(I)] | $\mathrm{R} 1=0.032, \mathrm{wR} 2=0.040$ |
| $R$ indices (all data) | $\mathrm{R} 1=0.0603, \mathrm{wR} 2=0.0896$ |
| Largest diff. peak and hole | 0.78 and -0.83 e. $A^{\wedge}-3$ |

## Experimental Details for the X-ray Crystallographic Study of 1,1'-Bis(triphenylmethyl)-4,4'biimidazole

| Empirical formula | $\mathrm{C}_{22.5} \mathrm{H}_{18} \mathrm{~N}_{2} \mathrm{Cl}$ |
| :---: | :---: |
| Formula weight | $\mathrm{M}=351.84 \mathrm{~g} \mathrm{~mol}^{-1}$ |
| Crystal system | monoclinic |
| Space group | C 2/c (No. 15) |
| Unit cell dimensions | $\mathrm{a}=14.7825(4) \AA \quad \alpha=90.000^{\circ}$ |
|  | $\mathrm{b}=13: 3779(2) \AA \quad \beta=93.2370(10)^{\circ}$ |
|  | $\mathrm{c}=18.3481(4) \AA \quad \gamma=90.000^{\circ}$ |
| Volume | 3622.71(14) $\AA^{3}$ |
| Z | $\mathrm{Z}=8$ |
| Density (calculated) | $\rho=1.290 \mathrm{~g} \mathrm{~cm}^{-3}$ |
| F(000) | 1472 |
| Diffractometer | Four circle diffractometer Siemens Smart |
| Mo K $\alpha$ Radiation | $\lambda=0.71073 \AA$ |
| Linear absorptions coefficient | $\mu\left(\mathrm{Mo} \mathrm{K} \alpha\right.$ ) $0.218 \mathrm{~mm}^{-1}$ |
| Data collection range | $4.10 \leq 2 \theta \leq 45$ |
| Index ranges | $-21 \leq \mathrm{h} \leq 20,-17 \leq \mathrm{k} \leq 19,-24 \leq 1 \leq 26$ |
| Temperature | 293 K |
| Programs | SHELX86, SHELX93 |
| Crystal dimension | $0.60 \times 0.53 \times 0.14 \mathrm{~mm}^{3}$ |
| Transmission coefficient $\mathrm{T}_{\text {Max }} / \mathrm{T}_{\text {Min }}$ | $0.9766 / 0.5171$ |
| Reflections collected | 13577 |
| Independent reflections | $4158\left[\mathrm{R}_{\text {(nti) }}=0.0850\right]$ |
| Refinement (on $\mathrm{F}^{2}$ ) | Full matrix least squares |
| Reflections observed | $\mathrm{n}=4146$ |
| No. of parameters refined | $\mathrm{p}=299$ |
| Largest peak/hole | 0.467 and -0.824 e. $\AA^{-3}$ |
| $\mathrm{GOF}=\mathrm{S}=\left[\Sigma\left[\mathrm{w}\left(\mathrm{F}_{0}{ }^{2}-\mathrm{F}_{\mathrm{c}}{ }^{2}\right)\right]^{2} \mid(\mathrm{n}-\mathrm{p})\right]^{1 / 2}$ | 1.028 |
| $\mathrm{R}=\Sigma \tau \mathrm{F}_{0} \sigma-\sigma \mathrm{F}_{\mathrm{c}} \tau \mid \Sigma \sigma \mathrm{F}_{0} \sigma$ | $0.0719\left[\mathrm{~F}_{0}>4 \sigma\left(\mathrm{~F}_{0}\right)\right], 0.1437$ (all data) |
| $\mathrm{wR}_{2}=\left[\Sigma\left[\mathrm{w}\left(\mathrm{F}_{\mathrm{o}}{ }^{2}-\mathrm{F}_{\mathrm{c}}{ }^{2}\right)^{2}\right] \mid \Sigma\left[\mathrm{w}\left(\mathrm{F}_{\mathrm{o}}{ }^{2}\right)\right]^{2}\right]^{1 / 2}$ | $0.1714\left[\mathrm{~F}_{0}>4 \sigma\left(\mathrm{~F}_{0}\right)\right], 0.2071$ (all data) |

[^0]:    ${ }^{a}$ See page xxii for compound abbreviations.

[^1]:    ${ }^{\text {a }}$ Error limits are $\pm 10 \%$.

[^2]:    ${ }^{\text {a }}$ Error limits are $\pm 10 \%$.

[^3]:    ${ }^{a}$ Error limits are $\pm 10 \%$.

[^4]:    ${ }^{\text {a }}$ Error limits are $\pm 12 \%$.
    b The error for these values is only $\pm 4 \%$.
    c The final concentration of $\left[\mathrm{Ru}(\mathrm{ma})_{2}(\mathrm{EF} 5)_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3} \cdot \mathrm{EtOH}$ was $48 \mu \mathrm{M}$ due to poor solubility.

[^5]:    ${ }^{\text {a }}$ Error limits are $\pm 5 \mathrm{ng} / 10^{6}$ cells.
    b The final concentration of $\left[\mathrm{Ru}(\mathrm{ma})_{2}(\mathrm{EF} 5)_{2}\right] \mathrm{CF}_{3} \mathrm{SO}_{3} \cdot \mathrm{EtOH}$ was $48 \mu \mathrm{M}$ due to poor solubility.
    c Data from Tables 6.3-6.6 (p. 138, 141, and 144) using the MDA-MB-435S cell line.
