ABSTRACT

Subsynchronous resonance (SSR) occurs in a series-capacitor-compensated power system when a mechanical mass-spring mode coincides with that of the electrical system. In this thesis, a complete high order model including mass-spring system, series-capacitor-compensated transmission line, synchronous generator, turbines and governors, exciter and voltage regulator is derived. Eigenvalue analysis is used to find the effect of capacitor compensation, conventional lead-lag stabilizer, loading and dampers on SSR. Finally, controllers are designed to stabilize multi-mode subsynchronous resonance simultaneously over a wide range of capacitor compensation.

ACKNOWLEDGEMENT

I wish to express my sincere gratitude to my supervisors, Dr. Y.N. Yu and Dr. M.D. Wvong, for their patience, guidance, many hours of consultation and valuzble advice during the course of the research work and writing of this thesis.

Financial support from a British Columbia Telephone Company Scholarship, a University of British Columbia Summer Research Fellowship and a teaching assistantship is gratefully acknowledged.

Thanks are also due to Mary Ellen Flanagan and Sannifer Louie for typing this thesis.

I am grateful to my parents and Mui Ha in Hong Kong for their patient understanding and encouragement throughout my university career.

1. INTRODUCTION

1.1 Subsynchronous Resonance [1]

To increase the power transfer capability of a power system, the use of series-capacitor-compensated transmission lines is the best alternative to the addition of transmission lines because of environmental considerations and the limited availability of right-of-way. They are also more economical than other methods such as HVDC. However, subsynchronous resonance (SSR) may occur and shaft damage may result. Two turbine shafts were severely damaged [2] at the Mohave generating station of the Southern California Edison Company because of the excessive torsional oscillations caused by interaction between the electrical resonance of the series-capacitor-compensated system and the natural modes of the multi-mass generator turbine mechanical system.

Subsynchronous resonance may occur in a system in the steady-state or transient state due to a system fault or major switching. The former may be called the steady-state subsynchronous resonance and the latter the transient subsynchronous resonance. The main problems are the self excitation, the torsional interaction, and the transient torques [3]. When SSR occurs, the synchronous machine is self-excited and behaves like an induction generator. If the negative resistance of the machine, as an induction generator, exceeds the total resistance of the external electrical system, self excitation of SSR occurs.

Torsional oscillation is due to the mechanical modes of the multi-mass turbine-generator system. The torsional frequencies are in the subsynchronous range. If the electrical resonant frequency is equal or close to a torsional mode, the rotor oscillations and the induced voltages will build up and the interaction between the electrical and

mechanical systems ensues [1,4].

Transient torques are caused by system disturbances on a series-capacitor-compensated line and the energy stored in the series capacitor produces large subsynchronous currents in the lines. When the frequency of the current coincides with the natural torsional frequency, transient torque results.

After the reported turbine shaft failures [3], corrective measures have been proposed. Some of them are under serious consideration and others already put into practice. Without too much modification to the existing system, the simplest way to avoid the subsynchronous resonance is to reduce the degree of capacitor compensation. Another suggestion is the installation of passive filter units in series with the generator transformer neutral at the high voltage side. Each filter unit is a high-Q parallel resonant circuit tuned to block the subsynchronous current at a particular frequency corresponding to one of the mechanical modes. Additional amortisseur windings on the pole faces can reduce the effective negative resistance [5]. Supplementary excitation control is being considered and the stabilizing signals are derived from rotor speed. Finally a subsynchronous overcurrent relay has been developed for the automatic protection of generating units in case of sustained subsynchronous oscillations.

1.2 Scope of the thesis

The widely accepted method for subsynchronous resonance studies in engineering practice consists of a two-step analysis [5]. The electrical and mechanical modes are determined separately. The transient electrical torque from the electrical system is calculated first and then applied to the mechanical system as a forcing function. In this thesis, a complete model including the electrical, mechanical and control systems

will be developed and presented in Chapter 2. By using eigenvalue analysis, the effect of various degrees of compensation, loading conditions and conventional supplementary excitation control on subsynchronous resonance will be examined in Chapter 3. For broad-band frequency multi-mode subsynchronous resonance control, linear optimal controllers will be designed in Chapter 4. A summary of all important results and conclusions will be presented in Chapter 5.

2. A COMPLETE POWER SYSTEM MODEL FOR SUBSYNCHRONOUS RESONANCE STUDIES

2.1 Introduction

For any dynamic or transient stability study of a power system, an accurate model of the system is required. In addition to the individual efforts [2,7,12], a benchmark model has been proposed by the IEEE Subsyn-
chronous Resonance Working Group for SSR studies [20]. In this chapter, a complete subsynchronous resonance model is presented, including steam turbines and generator multi-mass torsional system, the turbine torques and speed governor, the synchronous generator, the capacitor-compensated transmission lines, and the exciter and voltage regulator. A functional block diagram of the complete system is shown in Fig. 2-1.

2.2 The Steam Turbines and Generator Multi-Mass Torsional System

Assume that the steam turbine-generator set consists of one high-pressure steam turbine, one intermediate-pressure turbine, two low-pressure turbines, one generator rotor and one exciter, all mechanically coupled on the same shaft as shown in Fig. 2-2. They comprise a six-mass torsional system. For the purpose of analysis [13], they are considered to have concentrated masses and to be coupled by shafts of negligible mass and known torsional stiffness. Each mass is denoted by a circular disc, as in Fig. 2-3, with an inertia constant M_i , a positive torsional torque $K_i(\theta_{i+1} - \theta_i)$ on the left and a negative torque $-K_{i-1}(\theta_i - \theta_{i-1})$ on the right. There is an external torque T_i applied to the mass in a positive direction, an accelerating torque $M_i \dot{\omega}_i$ in the same direction and a damping torque $D_i \omega_i$ in the opposite direction. The net accelerating torque becomes

$$M_i \dot{\omega}_i = T_i - D_i \omega_i + K_i(\theta_{i+1} - \theta_i) - K_{i-1}(\theta_i - \theta_{i-1}) \quad (2-1)$$

where M_i = the inertia constant of i^{th} rotor
 θ_i = the rotational displacement for i^{th} rotor
 D_i = damping coefficient for i^{th} rotor
 $K_{i,i+1}$ = the torsional stiffness of the shaft between the i^{th} rotor and the $i+1^{\text{th}}$ rotor

By applying equation (2-1) to the six mass turbine-generator system, twelve differential equations are obtained:

$$\text{High Pressure } p\omega_6 = \frac{K_{56}}{M_6} \theta_5 - \frac{K_{56}}{M_6} \theta_6 - \frac{D_{66}}{M_6} \dot{\omega}_6 + \frac{T_{HP}}{M_6} \quad (2-2)$$

$$p\theta_6 = \omega_6 \omega_0 \quad (2-3)$$

$$\text{Intermediate Pressure } p\omega_5 = \frac{K_{56}}{M_5} \theta_6 - \frac{(K_{45} + K_{56})}{M_5} \theta_5 + \frac{K_{45}}{M_5} \theta_4 - \frac{D_{55}}{M_5} \dot{\omega}_5 + \frac{T_{IP}}{M_5} \quad (2-4)$$

$$p\theta_5 = \omega_5 \omega_0 \quad (2-5)$$

$$\text{Low Pressure 1 } p\omega_4 = \frac{K_{45}}{M_4} \theta_5 - \frac{(K_{34} + K_{45})}{M_4} \theta_4 + \frac{K_{34}}{M_4} \theta_3 - \frac{D_{44}}{M_4} \dot{\omega}_4 + \frac{T_{LP1}}{M_4} \quad (2-6)$$

$$p\theta_4 = \omega_4 \omega_0 \quad (2-7)$$

$$\text{Low Pressure 2 } p\omega_3 = \frac{K_{34}}{M_3} \theta_4 - \frac{(K_{23} + K_{34})}{M_3} \theta_3 + \frac{K_{23}}{M_3} \delta - \frac{D_{33}}{M_3} \dot{\omega}_3 + \frac{T_{LP2}}{M_3} \quad (2-8)$$

$$p\theta_3 = \omega_3 \omega_0 \quad (2-9)$$

$$\text{Generator } p\omega = \frac{K_{23}}{M_2} \theta_3 - \frac{(K_{12} + K_{23})}{M_2} \delta + \frac{K_{12}}{M_2} \theta_1 - \frac{D_{22}}{M_2} \dot{\omega} - \frac{T_e}{M_2} \quad (2-10)$$

$$p\delta = \omega \omega_0 \quad (2-11)$$

$$\text{Exciter } p\omega_1 = \frac{K_{12}}{M_1} \delta - \frac{K_{12}}{M_1} \theta_1 - \frac{D_{11}}{M_1} \dot{\omega}_1 \quad (2-12)$$

$$p\theta_1 = \omega_1 \omega_0 \quad (2-13)$$

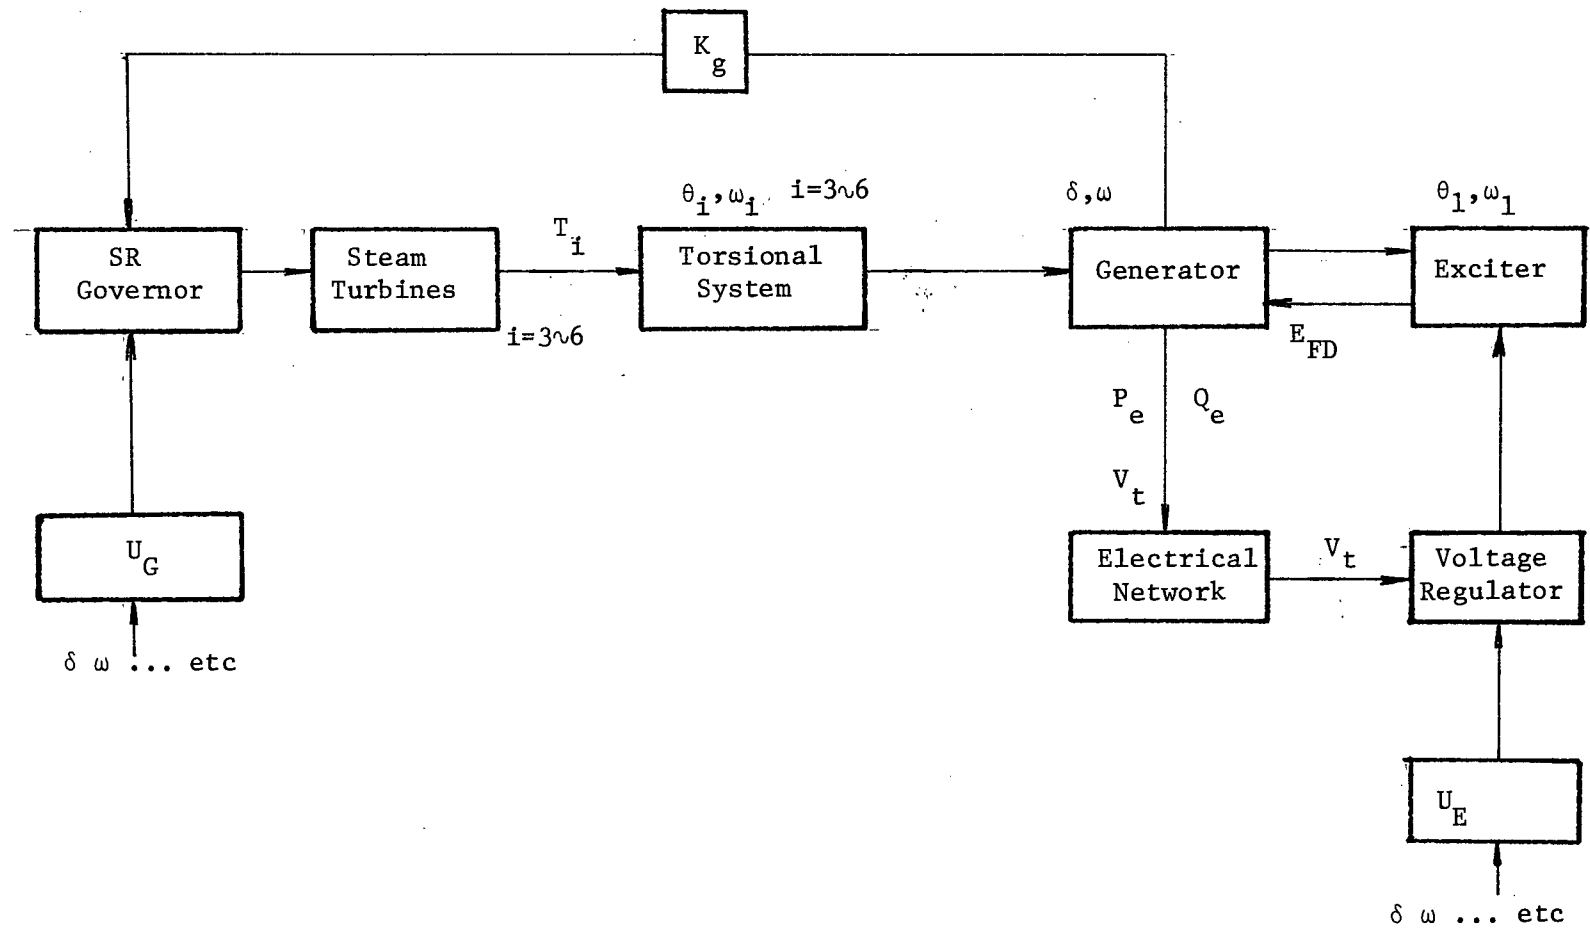

Fig. 2-1 A functional block diagram of the complete system for subsynchronous resonance studies.

The generator has an electric torque output T_e , and the exciter electric torque is neglected. Note that while angles are in radians, the speed is in p.u.;

$$\omega_0 = 1 \text{ p.u.} = 377 \text{ electrical radian/second}$$

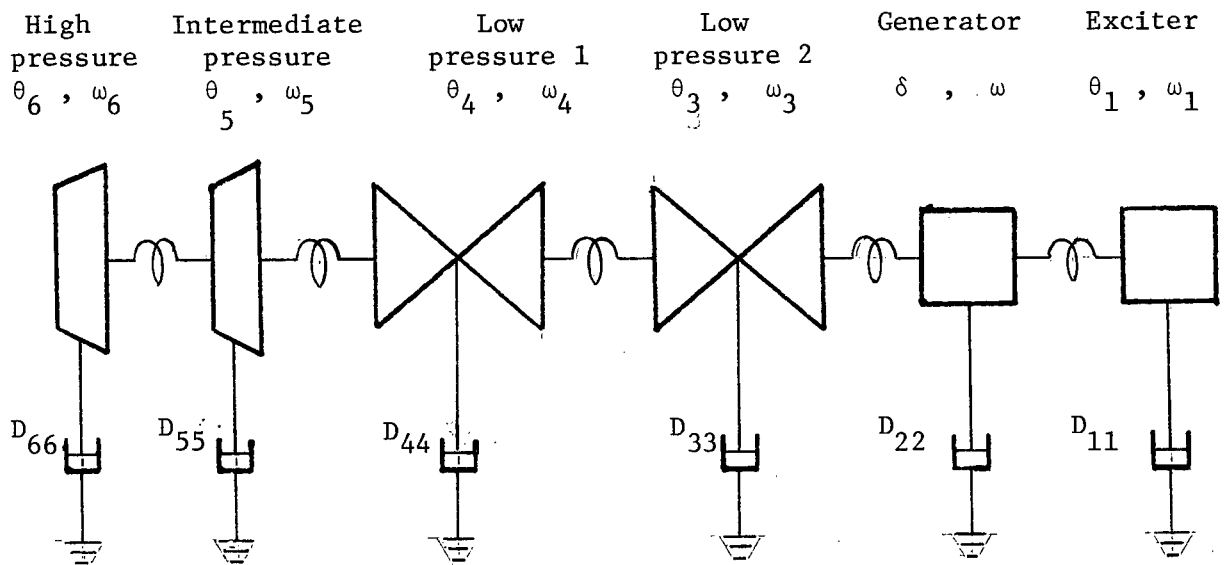

Fig. 2-2 Mechanical mass and shaft system

Fig. 2-3 Torques of a mass-shaft system

2.3 The Turbine Torques and Speed Governor

The steam turbine and speed governor representation is based on an IEEE committee report [14]. Usually the speed is sensed between the low-pressure turbine and the generator rotor. Combined with the speed reference, the speed deviation or error signal is derived and relayed through the actuator to activate the servomotor, which in turn opens or closes the steam valves. A block diagram [14] is shown in Fig. 2-4. For a linear study, the system equations may be written;

$$p \Delta a = \frac{K_g}{T_1} \Delta \omega - \frac{1}{T_1} \Delta a \quad (2-14)$$

$$p \Delta P_{GV} = \frac{1}{T_3} \Delta a - \frac{1}{T_3} \Delta P_{GV} \quad (2-15)$$

Fig. 2-4 A speed governor model for the steam turbine system

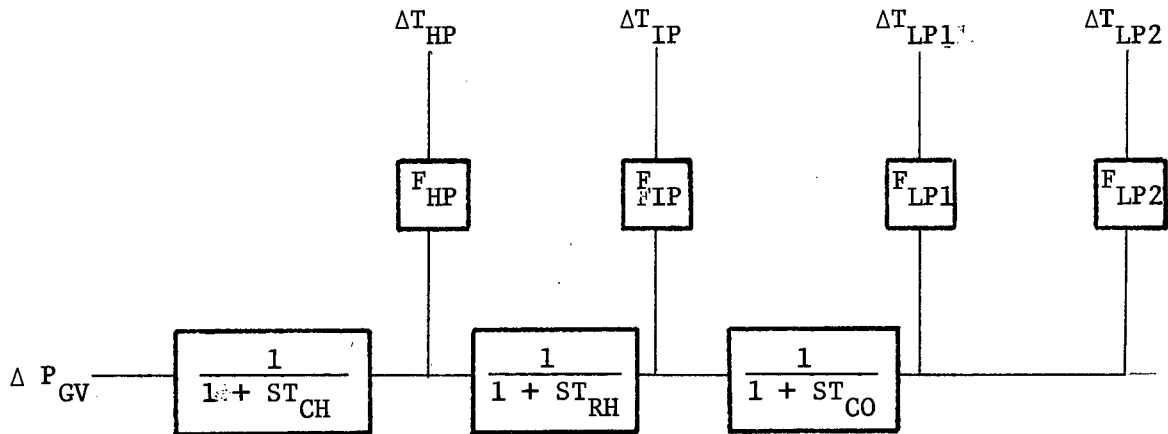

Fig. 2-5 AA Linear model of the steam turbine system

Fig. 2-5 shows a standard turbine representation for stability studies [14]. The system consists of one high-pressure, one intermediate-pressure and two low-pressure turbines. Their output torques are denoted by T_{HP} , T_{IP} , T_{LP1} , T_{LP2} , respectively. There is a reheater between high-pressure and intermediate-pressure stages, and crossover pipings between intermediate-pressure and low-pressure stages. The steam into the turbines flow through the governor-controlled valves at the inlet of the steam chest. The time constants of the steam chest, the reheater and the crossover piping are denoted by T_{CH} , T_{RH} , and T_{CO} , respectively. F_{HP} , F_{IP} , F_{LP1} , and F_{LP2} represent fractions of the total power developed in the various stages. Therefore

$$p \Delta T_{HP} = \frac{F_{HP}}{T_{CH}} \Delta P_{GV} - \frac{1}{T_{CH}} \Delta T_{HP} \quad (2-16)$$

$$p \Delta T_{IP} = \frac{F_{IP}}{F_{HP} \times T_{RH}} \Delta T_{HP} - \frac{1}{T_{RH}} \Delta T_{IP} \quad (2-17)$$

$$p \Delta T_{LP1} = \frac{F_{LP1}}{F_{IP} \times T_{CO}} \Delta T_{IP} - \frac{1}{T_{CO}} \Delta T_{LP1} \quad (2-18)$$

$$\Delta T_{PL2} = \frac{F_{LP2}}{F_{LP1}} \Delta T_{LP1} \quad (2-19)$$

2.4 The Synchronous Generator

The synchronous generator is assumed to have six windings. In addition to the d and q armature windings on the respective axes, there is a field winding f, a damper winding D on the d-axis and two damper windings Q and G on the q-axis. They are schematically shown in Fig. 2-6.

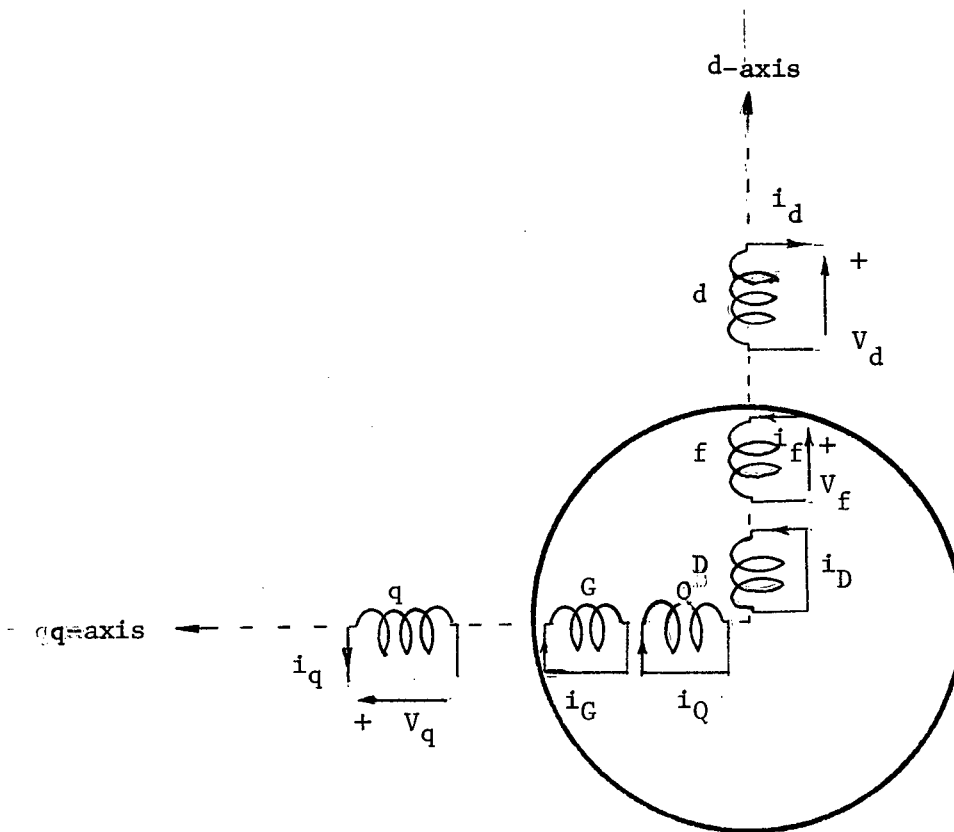

Fig. 2-6 A synchronous machine model

The voltage equations in the linear form are

$$\Delta V_d = p\Delta\psi_d - \omega_0\Delta\psi_q - \psi_{q0}\Delta\omega - R_a\Delta i_d$$

$$\Delta V_q = p\Delta\psi_q + \omega_0\Delta\psi_d + \psi_{d0}\Delta\omega - R_a\Delta i_q$$

$$\Delta V_f = p\Delta\psi_f + R_f \Delta i_f$$

$$0 = p\Delta\psi_D + R_D \Delta i_D$$

$$0 = p\Delta\psi_Q + R_Q \Delta i_Q$$

$$0 = p\Delta\psi_G + R_G \Delta i_G \quad (2-20)$$

where the flux linkages are

$$\begin{bmatrix} \Delta\psi_d \\ \Delta\psi_q \\ \Delta\psi_f \\ \Delta\psi_D \\ \Delta\psi_Q \\ \Delta\psi_G \end{bmatrix} = \frac{1}{\omega_0} \begin{bmatrix} -X_d & 0 & X_{ad} & X_{ad} & 0 & 0 \\ 0 & -X_q & 0 & 0 & X_{aq} & X_{aq} \\ -X_{ad} & 0 & X_f & X_{ad} & 0 & 0 \\ -X_{ad} & 0 & X_{ad} & X_D & 0 & 0 \\ 0 & -X_{aq} & 0 & 0 & X_Q & X_{aq} \\ 0 & -X_{aq} & 0 & 0 & X_{aq} & X_G \end{bmatrix} \begin{bmatrix} \Delta i_d \\ \Delta i_q \\ \Delta i_f \\ \Delta i_D \\ \Delta i_Q \\ \Delta i_G \end{bmatrix} \quad (2-21)$$

and the ψ 's, X 's, R 's and i 's are the per unit flux linkages, reactances, resistances and currents respectively.

The saturation in the iron circuit is neglected. The stator transient voltages $p\psi_d$ and $p\psi_q$, although normally neglected in stability studies [15,16] are retained in this study because the capacitor compensated transmission lines, to which the armature windings are connected in series, must be described by differential equations.

Fig. 2-7 A single line representation of the transmission line

In Fig. 2-7, V_d and V_q are d-q components of the terminal voltage V_c is the voltage across the capacitor and V_{ct} is the terminal voltage at the capacitor. The transformer is represented by a reactance X_t and a resistance R_t and the transmission line by a reactance X_e and a line resistance R_e .

Let the terminal voltage equations in a-b-c phase coordinates be

$$\begin{aligned}
 [V_t]_{a,b,c} &= [R] [I_t]_{a,b,c} + [L] \frac{d}{dt} [I_t]_{a,b,c} + [V_c]_{a,b,c} \\
 &\quad + [V_o]_{a,b,c}
 \end{aligned}
 \tag{2-22}$$

where $[R]$ = a resistance matrix: $R_t + R_e$

$[L]$ = an inductance matrix: $\frac{X_t + X_e}{\omega_0}$

Let Park's transformation matrix be

$$[T] = \begin{matrix} & \begin{matrix} d & q & o \end{matrix} \\ \begin{matrix} a \\ b \\ c \end{matrix} & \begin{bmatrix} \cos \theta & -\sin \theta & 1 \\ \cos(\theta-120) & -\sin(\theta-120) & 1 \\ \cos(\theta+120) & -\sin(\theta+120) & 1 \end{bmatrix} \end{matrix}
 \tag{2-23}$$

and the transformations are

$$[V]_{a,b,c} = [T][V]_{d,q,o} \quad \text{and} \quad [I]_{a,b,c} = [T][I]_{d,q,o} \quad (2-24)$$

Then we have

$$\begin{aligned} [V]_{d,q,o} = & [R][I]_{d,q,o} + [L]\frac{d}{dt}[I]_{d,q,o} + [L][T]^{-1}\frac{d}{dt}[T] \cdot [I]_{d,q,o} \\ & + [V_c]_{d,q,o} + [V_o]_{d,q,o} \end{aligned} \quad (2-25)$$

Note that

$$[T]^{-1}\frac{d}{dt}[T] = \begin{bmatrix} 0 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{bmatrix} \frac{d\theta}{dt} \quad (2-26)$$

The terminal voltage equation in d-q coordinates when linearized, becomes

$$\begin{bmatrix} \Delta V_d \\ \Delta V_q \end{bmatrix} = \begin{bmatrix} R_t + R_e & -X_t - X_e \\ X_t + X_e & R_t + R_e \end{bmatrix} \begin{bmatrix} \Delta i_d \\ \Delta i_q \end{bmatrix} + \frac{(X_t + X_e)}{\omega_o} p \begin{bmatrix} \Delta i_d \\ \Delta i_q \end{bmatrix} + \begin{bmatrix} \Delta V_{cd} \\ \Delta V_{cq} \end{bmatrix} + \begin{bmatrix} V_o \cos \delta_o \\ -V_o \sin \delta_o \end{bmatrix} \Delta \delta \quad (2-27)$$

where V_{cd} and V_{cq} are the d-q components of the voltage across the capacitor, and V_o the infinite bus voltage. The zero component equation is orthogonal to the other two equations and is usually neglected except for asymmetric loading. The capacitor equations may be written

$$[I]_{a,b,c} = [C] \frac{d}{dt} [V_c]_{a,b,c} \quad (2-28)$$

After transformation, it becomes

$$[I]_{d,q,o} = [C] \frac{d}{dt} [V_c]_{d,q,o} + [C][T]^{-1} \frac{d}{dt} [T][V_c]_{d,q,o} \quad (2-29)$$

which when linearized, gives

$$\begin{bmatrix} \Delta I_d \\ \Delta I_q \end{bmatrix} = \frac{1}{\omega_o X_c} p \begin{bmatrix} \Delta V_{cd} \\ \Delta V_{cq} \end{bmatrix} + \frac{1}{X_c} \begin{bmatrix} -\Delta V_{cq} \\ \Delta V_{cd} \end{bmatrix} \quad (2-30)$$

2.5 The Exciter and Voltage Regulator

The exciter and voltage regulator model in this thesis is based on an IEEE committee report [18] with some simplification. The regulator input filter time constant, the saturation function and the stabilizing feedback loop are neglected.

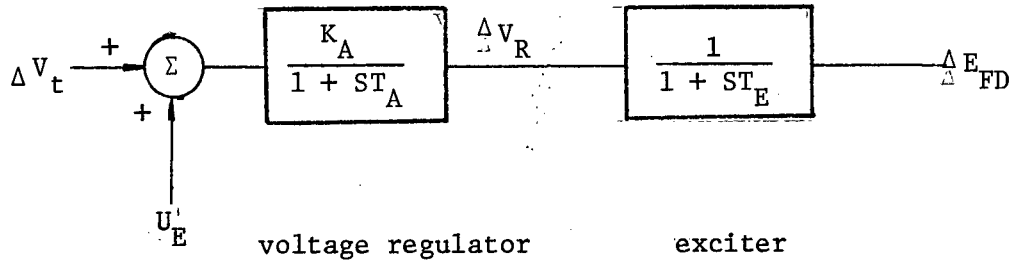

Fig. 2-8 Exciter and Voltage Regulator Model

In Fig. 2-8, V_t is the generator terminal voltage,

U'_E the supplementary control, K_A the voltage regulator gain, T_A its time constant, T_E the exciter time constant and E_{FD} a per unit output voltage of the exciter. Although the voltage limits are shown in the figure, they will be neglected in linear analysis. Mathematically we have

$$p \Delta V_R = \frac{K_A}{T_A} \Delta V_t + \frac{K_A}{T_A} u - \frac{1}{T_A} \Delta V_R \quad (2-31)$$

$$p \Delta E_{FD} = \frac{1}{T_E} \Delta V_R - \frac{1}{T_E} \Delta E_{FD} \quad (2-32)$$

where the linearized terminal voltage

$$\Delta V_t = \frac{V_{do}}{V_{to}} \Delta V_d + \frac{V_{qo}}{V_{to}} \Delta V_q \quad (2-33)$$

Substituting $\Delta V_d, \Delta V_q$ from equation (2-27) into equation (2-33) and the results into equation (2-31), we have

$$\begin{aligned}
 p \Delta V_R = & \frac{V_{do} K_A (X_t + X_e)}{V_{to} T_A \omega_o} p \Delta i_d + \frac{V_{qo} K_A (X_t + X_e)}{V_{to} T_A \omega_o} p \Delta i_q + \frac{K_A V_{do}}{T_A V_{to}} \Delta V_{cd} \\
 & + \frac{K_A V_{qo}}{T_A V_{to}} \Delta V_{cq} + \frac{K_A}{T_A V_{to}} [V_{do} (R_t + R_e) + V_{qo} (X_t + X_e)] \Delta i_d \\
 & + \frac{K_A}{T_A V_{to}} [-V_{do} (X_t + X_e) + V_{qo} (R_t + R_e)] \Delta i_q + \frac{K_A}{T_A} \Delta u - \frac{1}{T_A} \Delta V_R \\
 & + \frac{K_A V_o}{T_A V_{to}} [V_{do} \cos \delta_o - V_{qo} \sin \delta_o] \Delta \delta
 \end{aligned} \tag{2-34}$$

Fig. 2-9 shows a supplementary excitation control of the lead-lag compensation type [19].

Fig. 2-9 A supplementary excitation control

Mathematically,

$$K_s T p \Delta \omega - T p \quad b = \quad b \tag{2-35}$$

$$T_x p \quad b - T_y p \quad c = \quad c - \quad b \tag{2-36}$$

$$-T_y p \quad u + T_x p \quad c = \quad u - \quad c \tag{2-37}$$

2.6 State Equations for the Complete System

The component system equations previously derived can be combined into a single set of state equations in the form of

$$\dot{\underline{X}} = [\underline{A}] \underline{X} \quad (2-38)$$

where \underline{X} is the state variable vector and $[\underline{A}]$ the system matrix. Equation (2-38) can be conveniently partitioned

$$\begin{bmatrix} \dot{X}_I \\ \dot{X}_{II} \end{bmatrix} = \begin{bmatrix} A_{I,I} & A_{I,II} \\ A_{II,I} & A_{II,II} \end{bmatrix} \begin{bmatrix} X_I \\ X_{II} \end{bmatrix} \quad (2-39)$$

where X_I contains the state variables of the mechanical system and X_{II} those of the electrical system; namely

$$X_I = [\omega_1, \theta_{11}, \omega, \delta, \omega_3, \theta_3, \omega_4, \theta_4, \omega_5, \theta_5, \omega_6, \theta_6, a, P_{GV}, T_{HP}, T_{IP}, T_{LP1}]$$

$$X_{II} = [i_d, i_q, i_f, i_D, i_Q, i_G, V_{cd}, V_{cq}, V_R, E_{FD}]$$

$A_{I,II}$ represents the coupling between the two systems where the interaction occurs through the electrical torque T_e . Since

$$T_e = (\psi_d i_q - \psi_q i_d) \quad \text{per unit} \quad (2-40)$$

$$\Delta T_e = \{ (\psi_{do} \Delta i_q + i_{qo} \Delta \psi_d - \psi_{qo} \Delta i_d - i_{do} \Delta \psi_q) \} / \omega_o$$

$$= \{ (X_q - X_d) i_{qo} \Delta i_d + [(X_q - X_d) i_{do} + X_{ad} i_{fo}^e] \Delta i_q + i_{qo} X_{ad} \Delta i_f$$

$$+ i_{qo} X_{ad} \Delta i_D - i_{do} X_{aq} \Delta i_Q - i_{do} X_{aq} \Delta i_G \} / \omega_o \quad (2-41)$$

Next, the partitioned matrices $A_{II,I}$ and $A_{II,II}$ of the electrical system shall be first assembled in the form of

$$B \dot{X}_{II} = C_I X_I + C_{II} X_{II} \quad (2-42)$$

Then we have

$$\dot{X}_{II} = B^{-1} C_I X_I + B^{-1} C_{II} X_{II} \quad (2-43)$$

or
$$\dot{X}_{II} = A_{II,I} X_I + A_{II,II} X_{II}$$

where
$$A_{II,I} = B^{-1} C_I ; \quad A_{II,II} = B^{-1} C_{II} \quad (2-44)$$

Thus we have completed the derivation of the state equations for the overall system.

3. EIGENVALUE ANALYSIS OF THE SSR MODEL

3.1 Introduction

Eigenvalue analysis technique is useful in investigating the stability of systems. The complex eigenvalues are associated with oscillatory modes of the system and the real part of the eigenvalues provide the information on system damping. When an eigenvalue has a positive real part, instability of the system is indicated.

In this thesis the effect of capacitor compensation, conventional stabilizer and dampers will be investigated using the data taken from the benchmark model [20] Table 3-1.

3.2 The Effect of Capacitor Compensation

Fig. 3-1 and 3-2 show the eigenvalues of the system with various degrees of capacitor compensation, at a particular loading. The pair of eigenvalues corresponding to $\Delta\delta$ and $\Delta\omega$ of the synchronous machine have positive real parts when the compensation is 20% or less. The natural frequencies of the multi-mass torsional system are approximately 298, 203, 160, 127 and 99 radians/second which correspond to 47.4, 32.3, 25.5, 20.2, and 16 Hz respectively. By changing the degree of compensation, the natural oscillation frequency of the transmission system changes. When the frequency of the electrical mode is closed to a mechanical mode, SSR may occur. At 50% and 60% compensation, two mechanical modes are excited simultaneously.

3.3 The Effect of Conventional Stabilizer

Fig. 3-3 and 3-4 repeat the study of the effect of capacitor compensation, but with the addition of a conventional stabilizer of the lead-lag type. Whereas the pair of eigenvalues corresponding to $\Delta\delta$ and

$\Delta\omega$ of the synchronous machine were unstable for compensation below 30%, Fig. 3-1 shows they are substantially moved to the left half of the complex plane with the supplementary excitation control, Fig. 3-3. However, the lowest mechanical mode of 99 rad/sec is always excited and shifted to the right-half plane. This is in agreement with other findings [21, 22]. The damping of other mechanical modes is decreased slightly.

3.4 The Effect of Loading

The effect of different loading with and without stabilizer on SSR is shown in Fig. 3-5 and 3-6 respectively. Most of the eigenvalues do not change except those corresponding to the generator mechanical model. Generally the system becomes more unstable with more leading power factor. Most utilities operate their systems between 0.9 power factor lagging and unity power factor. For this reason, 0.9 power factor lagging is chosen for the studies here.

3.5 The Effect of Dampers

As reported [5] the addition of an amortisseur winding can reduce the possibility of SSR. For this investigation, the additional damper effect is represented by decreased damper impedance. When the total reactance of line and transformer is zero, SSR occurs. The result is shown in Table 3-2. The excited mode is damped out by decreasing the damper impedance which agrees with previous results [5].

4. MULTI-MODE TORSIONAL OSCILLATIONS STABILIZATION WITH LINEAR OPTIMAL CONTROL

Linear optimal control theory has been applied to the stabilizer design of power systems [23,8,24]. For practical applications, the state variables used in the design must be measurable. Another problem of optimal control design is the choice of the weighting matrices Q and R in the cost index. A simple procedure was proposed [8] which requires the state equations in the canonical form. The Q/R ratio in the procedure can be judiciously chosen.

4.1 State Equations With Measurable Variables

The state equations of the system was written in Chapter 2 in the form

$$\dot{X} = A X + B u \quad (4-1)$$

where A was given as (2-39). For an excitation control,

$$B = \begin{bmatrix} 0 & 0 & 0 & \dots & 0 & \frac{K_A}{T_A} \end{bmatrix}^t \quad (4-2)$$

as in (2-31). Let

$$Z = M X \quad (4-3)$$

where Z is the measurable variable vector. Then

$$\dot{Z} = M \dot{X} = M A M^{-1} Z + M B u$$

$$\text{or} \quad \dot{Z} = F Z + G u \quad (4-4)$$

$$\text{where} \quad F = M A M^{-1} \quad \text{and} \quad G = M B$$

Assume that all mechanical system variables, such as angles and speeds of every turbine rotor and that of generator and exciter; torques output from each stage of turbine and governor system and the electrical system variables such as generator power and current, voltage across the capacitor and to ground (generator side), damper currents and voltage output from voltage regulator and exciter, are measurable, then we have

For electrical power

$$\Delta P = V_{do} \Delta i_d + V_{qo} \Delta i_q + i_{do} \Delta V_d + i_{qo} \Delta V_q \quad (4-5)$$

By substituting V_d , V_q from equation (2-25)

$$\Delta P = m_{11} \Delta i_d + m_{12} \Delta i_q + m_{14} \Delta V_{cd} + m_{15} \Delta V_{cq} + m_{16} \Delta \delta \quad (4-6)$$

$$\text{where } m_{11} = V_{do} + (R_e + R_t) i_{do} + (X_e + X_t) i_{qo}$$

$$m_{12} = V_{qo} - (X_e + X_t) i_{do} + (R_e + R_t) i_{qo}$$

$$m_{14} = i_{do}$$

$$m_{15} = i_{qo}$$

$$m_{16} = V_o [i_{do} \cos \delta - i_{qo} \sin \delta]$$

For terminal current

$$\Delta i_t = \frac{i_{do}}{i_{to}} \Delta i_d + \frac{i_{qo}}{i_{to}} \Delta i_q \quad (4-7)$$

$$\text{or } \Delta i_t = m_{21} \Delta i_d + m_{22} \Delta i_q$$

$$\text{where } m_{21} = \frac{i_{do}}{i_{to}}, \quad m_{22} = \frac{i_{qo}}{i_{to}}$$

For voltage across the capacitor

$$\Delta V_{ct} = \frac{V_{cdo}}{V_{co}} \Delta V_{cd} + \frac{V_{cqo}}{V_{co}} \Delta V_{cq} \quad (4-8)$$

$$\text{or } \Delta V_c = m_{44} \Delta V_{cd} + m_{45} \Delta V_{cq}$$

$$\text{where } m_{44} = \frac{V_{cdo}}{V_{co}}, \quad m_{45} = \frac{V_{cqo}}{V_{co}}$$

For voltage at the terminal of the capacitor.

As shown in Fig. 2-7, V_{ct} is the voltage at the generator side of the capacitor with respect to ground

$$\Delta V_{ct} = \frac{V_{ctdo}}{V_{cto}} \Delta V_{ctd} + \frac{V_{ctqo}}{V_{cto}} \Delta V_{ctq} \quad (4-9)$$

where V_{ctd} and V_{ctq} are the d, q components of V_{ct} and can be expressed in terms of the voltage across the capacitor and infinite bus voltages.

$$\Delta V_{ctd} = \Delta V_{cd} + V_o \cos \delta \Delta \delta \quad (4-10)$$

$$\Delta V_{ctq} = \Delta V_{cq} - V_o \sin \delta \Delta \delta$$

$$\text{or} \quad \Delta V_{ct} = m_{54} \Delta V_{cd} + m_{55} \Delta V_{cq} + m_{56} \Delta \delta \quad (4-11)$$

$$\text{where} \quad m_{54} = \frac{V_{ctdo}}{V_{cto}}, \quad m_{55} = \frac{V_{ctqo}}{V_{cto}}$$

$$m_{56} = [V_{ctdo} \cos \delta - V_{ctqo} \sin \delta] \frac{V_o}{V_{cto}}$$

Besides m_{11} , m_{22} , m_{44} and m_{55} , the other main diagonal elements are unity. Other off-diagonal elements are zero except those already derived.

4.2 State Equations in Canonical Form

A design procedure has been developed utilising state equations in canonical form [8]:

$$F_o = \begin{bmatrix} 0 & 1 & . & . & . & 0 \\ . & 0 & 1 & . & . & . \\ . & . & . & . & . & . \\ . & . & . & . & . & . \\ .. & . & . & . & 1 & . \\ 0 & .. & . & . & . & 0 & 1 \\ -\alpha_1 & -\alpha_2 & . & . & . & -\alpha_{n-1} & -\alpha_n \end{bmatrix} \quad (4-12)$$

$$\text{Let} \quad Z = T Y \quad (4-13)$$

we shall have

$$\dot{Y} = T^{-1} \dot{Z} = F_0 Y + G_0 U \quad (4-14)$$

$$\text{where } F_0 = T^{-1} F T \quad (4-15)$$

$$\text{and } G_0 = T G = [0 \ 0 \ 0 \ \dots \ 1]^t \quad (4-16)$$

The transformation matrix T can be found as follows:

Since the eigenvalues remain unchanged with similarity transformation, we shall have

$$|\lambda I - F| = (\lambda - \lambda_1) (\lambda - \lambda_2) \dots (\lambda - \lambda_n) = 0 \quad (4-17)$$

and

$$|\lambda I - F_0| = \lambda^n + \alpha_n \lambda^{n-1} + \alpha_{n-1} \lambda^{n-2} + \dots + \alpha_1 = 0 \quad (4-18)$$

where $\lambda_1, \lambda_2, \dots, \lambda_n$ are the eigenvalues of the system. The α 's can be determined from (4-16) and (4-17),

$$\begin{aligned} \alpha_n &= - \sum_{i=1}^n \lambda_i \\ \alpha_{n-1} &= \lambda_1 \lambda_2 + \lambda_1 \lambda_3 + \dots + \lambda_2 \lambda_3 + \dots + \lambda_{n-1} \lambda_n \\ \alpha_{n-2} &= -\lambda_1 \lambda_2 \lambda_3 - \lambda_1 \lambda_2 \lambda_4 - \dots - \lambda_{n-2} \lambda_{n-1} \lambda_n \\ &\vdots \\ \alpha_1 &= (-1)^n \prod_{i=1}^n \lambda_i \end{aligned} \quad (4-19)$$

Let the transformation T matrix be written as

$$T = [T_1, T_2, T_3, \dots, T_n] \quad (4-20)$$

where $T_1, T_2, T_3, \dots, T_n$ are the column vectors of T matrix. From (4-15)

and (4-20), we have

$$T F_0 = F T \quad ($$

$$\text{or} \quad [T_1, T_2, T_3, \dots T_n] F_0 = F[T_1, T_2, T_3, \dots T_n] \quad (4-21)$$

From (4-16) and (4-21), we have

$$T_n = G \quad (4-22)$$

Hence, we can compute $T_1, T_2, T_3 \dots T_n$ by using the following recursive formula

$$T_{n-i} = F T_{n-i+1} + \alpha_{n-i+1} G \quad i = 1, 2, 3, \dots n-1 \quad (4-23)$$

and

$$F T_1 + \alpha_1 G = 0 \quad (4-24)$$

The condition of (4-24) may not be met due to the accumulated computation errors. Let $T_1, T_2, T_3, \dots T_n$ be the computed results and $\hat{T}_1, \hat{T}_2, \hat{T}_3, \dots \hat{T}_n$ be correct values

$$F \hat{T}_1 + \alpha_1 G = 0$$

$$F T_1 + \alpha_1 G = \hat{\epsilon} \epsilon \quad (4-25)$$

and the error

$$\hat{T}_1 - T_1 \triangleq n_1 \quad (4-26)$$

$$\text{Then} \quad n_1 = -F^{-1} \epsilon \quad (4-27)$$

Similarly,

$$F \hat{T}_2 + \alpha_2 G = \hat{T}_1$$

$$F T_2 + \alpha_2 G = T_1 \quad (4-28)$$

$$\text{and} \quad n_2 = F^{-1} n_1 \quad (4-29)$$

Therefore,

$$n_i = F^{-1} n_{i-1} \quad i = 2, 3, 4, \dots n \quad (4-30)$$

$$\hat{T}_i = n_i + T_i$$

4.3 Linear Optimal Control Design

The system equations in canonical form were

$$\dot{Y} = F_o Y + G_o U \quad (4-14)$$

The characteristic equation of the open loop system is

$$|\lambda I - F_o| = \lambda^n + \alpha_n \lambda^{n-1} + \alpha_{n-1} \lambda^{n-2} + \dots + \alpha_1 \quad (4-31)$$

Let the desired eigenvalues of the closed-loop system be $\hat{\lambda}_1, \hat{\lambda}_2, \hat{\lambda}_3, \dots, \hat{\lambda}_n$

The new characteristic equation will be

$$\begin{aligned} & (\lambda - \hat{\lambda}_1) (\lambda - \hat{\lambda}_2) (\lambda - \hat{\lambda}_3) \dots (\lambda - \hat{\lambda}_n) \\ &= \lambda^n + \hat{\alpha}_n \lambda^{n-1} + \hat{\alpha}_{n-1} \lambda^{n-2} + \dots + \hat{\alpha}_1 = 0 \end{aligned} \quad (4-32)$$

Since characteristic equation of the closed loop system is

$$\begin{aligned} & |\lambda I - (F_o - G_o S_o)| \\ &= \lambda^n + (\alpha_n + \beta_n) \lambda^{n-1} + (\alpha_{n-1} + \beta_{n-1}) \lambda^{n-2} + \dots + (\alpha_1 + \beta_1) \\ &= 0 \end{aligned} \quad (4-33)$$

where

$$U \triangleq -S_o Y \quad (4-34)$$

Equating (4-32) to (4-33) gives

$$\hat{\alpha}_i - \alpha_i = \beta_i \quad i = 1, 2, 3, \dots, n \quad (4-35)$$

$$\text{and } S_o = [\beta_1, \beta_2, \beta_3, \dots, \beta_n] \quad (4-36)$$

Finally, the linear optimal controller in measurable state variables

$$U \triangleq -S_o Y$$

or

$$U \triangleq -S_o T^{-1} Z \quad (4-37)$$

4.4 Stabilization of SSR

Because of the number of state variables which can be measured, the 22nd order and 19th reduced order models are used for the linear optimal control design. Eigenvalue analysis shows that all the important mechanical and electrical eigenvalues are essentially unchanged; Table 4-1.

Single mechanical mode stabilization

At 30% compensation and 0.9 power factor lagging of the reduced 22nd order system without stabilizer, the 204 rad./sec. or 32.5 hertz mechanical mode is excited and has negative damping (eigenvalues with positive real part). By utilizing the design procedure described in this chapter, an optimal controller can be designed to shift the eigenvalues from $+0.1541 \pm j204.35$ to $-6.500 \pm j204.35$ and another mechanical mode which is barely stable from $-0.08805 \pm j8.4938$ to $-6.000 \pm j8.4938$. All eigenvalues are stabilized as shown in Table 4-2. The controller is 7.8 $(7.823\Delta\omega_1, 0.0964\Delta\theta_1, -183.005\Delta\omega, -8.801\Delta\delta, 192.487\Delta\omega_3, -3.398\Delta\theta_3, 65.534\Delta\omega_4, 7.448\Delta\theta_4, -1.336\Delta\theta_5, -47.478\Delta\omega_6, -2.738\Delta\theta_6, -29.746\Delta P, 28.645\Delta i_t, 1.454\Delta i_f, 1.475\Delta i_D, -5.931\Delta i_Q, -5.929\Delta i_G, -60.094\Delta V_c, 35.987\Delta V_{c_t}, -0.000260\Delta V_R, -0.00259\Delta E_{FD})$.

Stabilization of two mechanical modes simultaneously

For the same system but with 50% compensation, two mechanical modes were excited $+0.1560 \pm j202.68$ and $+0.9101 \pm j161.42$ were excited simultaneously. Another optimal controller is designed to shift the two mechanical modes to $-6.500 \pm j202.68$ and $-3.500 \pm j161.42$ as shown in Table 4-3. The controller is $(1.124\Delta\omega_1, -4.959\Delta\theta_1, -23.848\Delta\omega, 189.462\Delta\delta, 13.843\Delta\omega_3, -321.301\Delta\theta_3, 24.286\Delta\omega_4, 147.568\Delta\theta_4, -6.018\Delta\omega_5, 4.467\Delta\theta_5, -9.927\Delta\omega_6, -25.064\Delta\theta_6, -26.719\Delta P, 29.533\Delta i_t, -1.030\Delta i_f, -1.007\Delta i_D, -6.711\Delta i_Q, -6.712\Delta i_G, -22.422\Delta V_c, 31.169\Delta V_{c_t}, -0.000278\Delta V_R, -0.00264\Delta E_{FD})$.

Low Order Stabilization Design

Although the two controllers designed by the procedure presented in this chapter have been proved to be effective in stabilizing the system, the damper currents are not directly measurable. Still another linear optimal controller is designed for the system, without the need for damper currents. The equations associated with the damper windings are dropped, resulting in a 19th order system. The controller is $(1.84\Delta\omega_1, 1.01\Delta\theta_1, -41.51\Delta\omega, -30.63\Delta\delta, 54.51\Delta\omega_3, 39.93\Delta\theta_3, 7.37\Delta\omega_4, -5.77\Delta\theta_4, -6.41\Delta\omega_5, -3.32\Delta\theta_5, -7.46\Delta\omega_6, -2.16\Delta\theta_6, -1.66\Delta P, 2.63\Delta i_t, -0.872\Delta i_f, -2.26\Delta V_c, -2.35\Delta V_{tc}, -0.000295\Delta V_R, -0.00274\Delta E_{FD})$, and the eigenvalues of the system with and without the controller are shown in Table 4-4. Finally the controller is tested on the original system for various degrees of compensation. The results are plotted in Fig. 4-1. It is found that the controller designed for the 19th order model with 30% compensation, not only can stabilize the original 27th order system for 30% compensation but also can stabilize the original system from 10 to 70% compensation. This proves the effectiveness of such controller design in wide-range-compensation multi-mode SSR stabilization.

5. CONCLUSIONS

A high-order power system model for subsynchronous resonance studies is developed. The model includes mass-spring system, synchronous machine, series capacitor compensated transmission lines, turbines and governor, voltage regulator and exciter. The transient terms $p\psi_d$ and $p\psi_q$ are included.

From eigenvalue analysis, it is found that by changing the degree of compensation the frequency of the electrical mode will be changed and that, in some cases, even more than one mechanical mode can be excited at the same time. When a conventional lead-lag supplementary excitation control for the stabilization of small oscillations is included, it has an adverse effect on the other mechanical modes close to the small oscillation mode. Such finding is in agreement with other previous work [22]. When the damper impedance is decreased, it does reduce the possibility of SSR under ideal conditions [5].

Linear optimal controllers based upon an earlier developed method [8] are designed. Two controllers are designed with a reduced 22nd order model and one with a reduced 19th order model and the latter controller not only can stabilize the original 27th order system for 30% compensation, but also can stabilize the system for wide-range compensation and multi-mode SSR.
