ABSTRACT

Theory of ecological (biophysical) land classification is presented. The theory of integrated ecological land classification, mapping and analysis is applied to recreational land planning. An approach to recreational site-suitability analysis appropriate for reconnaissance level inventories and analyses of recreation capabilities is presented.

Clague Mountain Park, Kitimat, B.C. served as a case study for applying the recreation site-suitability analysis approach developed. Landforms, identified using the Terrain Classification System (Ministry of Environment, 1978), served as the basis upon which selected ecologically-significant parameters were inventoried and analyzed. The parameters used in this analysis included topography, depth to bedrock, frost action, flood hazard, vegetation, climate and various soil characteristics, including moisture regime, texture, stoniness, rockiness, permeability and erosion hazard. The activities considered in this analysis included camping (intensive), hiking (summer), picnicking/day use, cross-country skiing, downhill skiing, mountain climbing/mountaineering, tobogganning, snowmobiling and snowshoeing.

The recreational suitability of the park was summarized in tables and maps. It was found that this site-suitability analysis approach provided an effective means for establishing an area's recreational suitability. It is recommended that the findings of this analysis be used to assist in any future recreation planning and management within the park.

ACKNOWLEDGEMENTS

Dr. W. Rees of the School of Community and Regional Planning and Dr. P.J. Dooling of the Faculty of Forestry are thanked for their time and efforts in the review of this thesis. My wife, Joan Thelma Chess, provided invaluable support and advise during the writing of this thesis. Jon, my youngest brother, is thanked for his assistance in the collection of field data.

The City of Kitimat is thanked for their financial support and direction. Lastly, I want to thank B. Weisman and the School of Community and Regional Planning for the opportunity to develop more fully my skills and knowledge of resource planning and development.

1.0 INTRODUCTION

Efficient and effective natural resources planning and management requires a sound generally accepted approach to resources inventory and analysis. The purpose of this thesis is to discuss the theories and concepts of ecological (biophysical) land classification and to show how it can serve as a partial basis for undertaking outdoor recreation suitability analysis. The major premise of this thesis is that, the interactive physical and biological factors of the environment can be used as indicators of the land's ability to sustain specific uses. Such environmental attributes can govern the form, intensity, duration and general sustainability of resource uses in given landscapes. This approach is not all encompassing for it does not account for the contributions of social, historical, archeological, political and economic factors.

In this thesis a small municipal park situated in northwestern British Columbia was assessed as to its suitability for each of nine selected outdoor recreational activities. This analysis of Clague Mountain Park, Kitimat, B.C., was undertaken using established, activity-specific sets of ecologically significant environmental parameters. The activities included were camping (intensive), hiking (summer), picnicking/day use, cross-country skiing, downhill skiing, mountain climbing/mountaineering, tobogganning, snowmobiling and snowshoeing.

- 1 -

The objectives of this thesis are:

- to illustrate the theory and potential contribution of integrated land classification, mapping and analysis to more efficient and effective planning of the recreational resource base,
- 2. to present sets of ecologically-significant parameters for specific recreational activities which will aid in the establishment of the limitation of given landscapes for each of these activities,
- 3. to develop an approach to recreational site-suitability analysis appropriate for reconnaissance level inventories and analyses of the recreational capability of the Coast Mountain region of British Columbia,
- 4. to apply the recreational site-suitability approach developed to Claque Mountain Park, Kitimat, B.C.,
- 5. and, to derive recommendations that will aid in the future planning, development and management of Clague Mountain Park.

2.0 THEORY OF ECOLOGICAL (BIOPHYSICAL) LAND CLASSIFICATION 2.1 Concepts of Classification

Assume that an area is to be inventoried, classified and interpreted for its suitability for recreation development, what is the "best" or most "optimum" classification scheme to use? As might be suspected, there is no "best" approach to land classification. Various systems of land classification are contrivances developed to suit specific needs, hence they

- 2 -

are not truths than can be discovered. Classification is the ordering or arranging of objects into groups or sets based on similarities or relationships. The social, economic, administrative and environmental characteristics of the environment and their interrelationships foster the development and application of a host of classification schemes. Such schemes are based on land characteristics, present use, use capabilities, recommended use, need for effectuation of programs and other criteria that aid in meeting societys' needs and aspirations.

If supply inventory and classification systems are to be useful they should meet the following requirements:

- "The classification must be as objective as possible to adequately define the land classes in terms of inherent biophysical potential for resource production." (Driscoll, 1978).
- 2. The landscape features upon which the classes are based should be permanent. "It is understood that some elements of the system; for example vegetation and soil, change as a result of resource management practises. However, some diagnostic characteristics (land surface configuration and climate) remain relatively permanent and the class orders of the classification can be inferred by induction or deduction." (Driscoll, 1978).
- 3. The system must be flexible, general and of use over defined geographic areas if it is to be functional in predicting a range of information over a large number of environmental situations.

- 3 -

- 4. From a practical standpoint it should be formed on concepts and logic that are understood by non-technical people, permit inclusion into an overall empirical computer-oriented information system, and be designed and documented for ease of identification and mapping of field sites.
- 5. Selected classes should facilitate inductive, as well as deductive assessments to be developed in the context of the feature of interest or the particular purpose of the study. Different fields of generalizations call for different classifications (Bailey <u>et al</u>, 1978).
- 6. The classification system should facilitate the collection of remotely sensed data at various scales of intensity and at different times of the year (sequential photographic and remotely sensed imagery).

As indicated previously, one of the major applications of land classification systems has been in the derivation of land capability or capacity estimates, be it for recreational pursuits or other of mans' activities. Classification provides a framework for an interdisciplinary inventory of the resources which control land capability (capacity). "Land capability" in this context refers to the physical carrying capacity of an area as defined by the inherent ability of the landscape to sustain a given use (Block, 1976). Land units will be assessed in terms of their capacities to support a range of selected recreational activities. In this thesis land unit suitability is the inherent capacity of a land unit to support a given use but does not include the land unit's ability to attract such use, accessibility to it nor any social or economic considerations.

2.2 Concept of Ecological (Biophysical) Classification

What does ecological (biophysical) land classification This term is used to denote an integrated approach to mean? land survey, in which land is inventoried, classified and mapped as distinct ecosystems (Welch, 1977; Rowe, 1978; Wiken, 1978). "Land" includes both biotic (physical-chemical) components of the environment and their interactions as they influence human activities. To establish a sense of order and consistency in land classification, the Canada Committee on Ecological (Biophysical) Land Classification (CCELC) proposed that this integrated approach be known as "ecological (biophysical) land classification" (ELC). The primary objective of CCELC is, "to encourage the continued development and to promote the application of a uniform ecological (biophysical) approach to land classification for resource planning, management and environmental impact assessment purposes" (Wiken, 1978). In effect the CCELC has taken on the responsibility to co-ordinate the development of the Canadian Land Classification System.

Ecological land classification attempts to express the interactive character of the lands' components and human

- 5 -

activities. A better understanding of these interactive properties facilitates improved management of the natural and anthropogenic resource base. A more detailed discussion of ELC is given in 2.3. Establishing the interrelationships in a given ecosystem can be difficult, as ecosystem behavior is not linear. ELC attempts to simplify these relationships between different areas of land in a spatial hierarchical fashion.

Over the past four decades numerous ELC studies have been undertaken in Canada, with subsequent studies improving the methods and findings of previous ones. In a vast and unsettled country like Canada, the ELC approach has proven invaluable for differentiating and classifying ecologicallysignificant segments of the land surface. For areas which warrant more detailed study the ELC's hierarchical framework allows a more refined evaluation. Lacate (1969) proposed an ELC system which recognized several levels of generalization. This system has become the "model" for approaches in Canada. The four levels which comprise Lacate's system are:

> Land Region: an extensive area of contiguous landscapes with a complex of physiographic patterns distinguished by regional climate as expressed by vegetational complexes. Boundary delineation is on the basis of the macro biota-soil indicators of latitudinal and longitudinal climatic change.

Land District: is a component of Land Region, being

- 6 -

characterized by a distinctive pattern of relief, geological structure, geomorphic evolution and associated regional vegetation. Boundary delineation is on the basis of macro changes in relief and/or bedrock geology. Land System: is a component of a Land District, being characterized by a recurring pattern of landforms, soils and vegetation. Mapping units at the Land System level are identifiable on airphotos primarily as patterns of landforms and vegetation. Boundary delineation is on the basis of meso changes in surficial geology and landform.

Land Type: is a component of Land System, being characterized as a topographic combination of soil texture, drainage and a succession of vegetation. The Land Type is the fundamental land classification unit; often being used as a basis for rating the biological carrying capacity of a given area or for other resource management purposes for which more specific and highly detailed capability ratings might be required. Boundaries are delineated on the basis of changes in slope and in variations in soil materials and depth. (Lacate, 1969; Oswald and Senyk, 1977; Rowe, 1978.)

2.3 Landform and Related Ecological Parameters

Having introduced an overall framework and the major premises of ELC, the parameters that are deemed "ecologically-

- 7 -

significant" in ELC will be discussed. Before proceeding it should be noted that although there is a common approach to ELC, the selection of parameters is dependent on local needs and available methods of collection (Welch, 1977; Rowe, 1978).

In practise ELC surveys rely on perceived boundaries which define areas displaying certain uniform or interconnected traits. Parameters selected to describe these traits serve as benchmark indicators or generators of function and process in the landscape. Selection of parameters will be dependent on limitations in time, monies, manpower and other resources, recognition of local needs and project objectives.

Landforms are one of the more commonly used and interpreted landscape features (Gimbarzevsky, 1978b). Landforms are defined as:

- a) ".... natural terrain units (including geologic elements and transported or residual soils) that, where developed under similar conditions of climate, weathering, erosion and mass wasting, will exhibit a predictable range of physical and visual characteristics. Therefore, soils developed from similar parent materials (under similar conditions) are related and have similar engineering properties." (Way, 1978).
- b) "The various shapes of the land surface resulting from a variety of actions such as deposition or sedimentation (eskers, lacustrine basins), erosion (gullies, canyons) and earth crust movements (mountains)." (Agric. Can., 1976).

- 8 -

c) ".... areas of land or topographic features that are defined in terms of their shapes and slope patterns, the materials that produce the relief, and, wherever possible, in terms of their mode of origin. Landforms are areas of land, or topographic features, that provide the framework to which patterns and changes in vegetation and soils can be geographically related." (Lacate, 1969).

Recognition and interpretation of landforms and associated surficial geology serves to establish a geographic framework to which soil, vegetation, climate and land use information can be related and subsequently extrapolated over adjacent landscapes. In British Columbia the Resource Analysis Branch's Terrain Classification System is a prime example of how landform recognition and interpretation can serve as a framework to which other ecological parameters can be related (Min. of the Envir., 1978) (*refer to Appendix VIII).

The classification system used to assess the landform features, soils and parent materials in this thesis is that proposed by the RAB (Min. of the Envir., 1978). Further, in this thesis all references made to either "land units" or "land systems" imply the areas of the landscape as defined by Lacate's (1969) "Land System" level of classification.

In practise it has been shown that aerial photo interpretation techniques facilitate systematic mapping of the physical characteristics of the landscape (Gimbarzevsky, 1978b).

- 9 -

The combined use of existing reports and maps, ground checks and airphoto interpretations enables one to classify and accurately delineate landforms based on observed or deduced physical and biological landscape attributes. The inherent attributes of landform govern the sustainability for selected resource uses. As a prerequisite to sound land planning and management it is imperative that a comprehensive and quantitative knowledge of the ecological attributes of the landscape be attained (Jurdant <u>et al</u>, 1974).

The characteristics of natural vegetation have been found to be closely linked with landform. The integration of vegetation into ecological land inventory has proven inadequate due to the lack of a generally accepted descriptive method for vegetation, the absence of a framework for classifying Canadian vegetation types, the rapid reaction of vegetation to disturbance and the presence of variable vegetation cover on similar landforms. There is a need for parameters that are independent of successional or man-induced changes (Gimbarzevsky, 1978b; Rowe, 1978). Vegetation is usually inventoried and classified on the basis of vegetation structure, such as stratification, height, percent cover and crown closure, species composition by stratum and species abundance (numbers and percent coverage). Although vegetation is not as suitable as landform, as a framework for ELC, it has proven useful for inventorying and interpreting for wildlife, recreation, timber and other resources and resource uses. Vegetation is

- 10 -

an indicator of soil condition, hence, facilitates the identification and mapping of soil texture, permeability, salinity, fertility, moisture and drainage classes, depth to seasonal watertable and soil taxonomic classes (Lacate, 1969; Gimbarzevsky, 1978b; Way, 1978).

In British Columbia, vegetation classification has been heavily influenced by Krajina's (1969) concept of Biogeoclimatic Zonation. Krajina's approach expresses the combined influence of climate and physiography on the dominant vegetation, with each Biogeoclimatic Zone being named after the dominant climatic climax tree species on mesic sites within each Zone. Although it is one of the most ecologically advanced vegetation classification systems in use today, it suffers from some poorly defined boundaries arising from insufficient data (U.B.C. Forest Club, 1971).

In this thesis the vegetation-related parameters were based on the inherent characteristics of the Coastal Western Hemlock Zone (Wet Subzone), the Mountain Hemlock Zone (Forest and Parkland Subzones) and the Alpine Zone. Realizing the drawbacks of integrating vegetation into ELC, it nevertheless plays an important role in establishing a sense of the ecological unity of an area.

Climate represents the average weather conditions of an area and, hence, limits the existing or planned activities in an area. Climate is reflected in an area's biological activity, which, in turn, determines the suitability of an

- 11 -

area for a variety of uses, i.e., valley bottoms, with their normally higher levels of biological productivity, would probably be more suitable for a wider range and greater intensity of use than high elevation alpine areas, characterized by short growing seasons and extremes in temperatures, wind and insolation. Climate is often deduced from patterns of vegetation, landform and drainage characteristic of an area (Oswald and Senyk, 1977; Rowe, 1978).

In rugged mountainous areas of British Columbia the varied macro-relief has pronounced modifying influences on regional climates (Oswald and Senyk, 1977). On a larger scale, landforms can have pronounced influences on their surrounding micro-climates. Slopes and aspects will determine the amounts of solar radiation, wind and precipitation landforms will receive (Gimbarzevsky <u>et al</u>, 1978). Air temperature, precipitation, wind, relative humidity and solar radiation are the climatic categories often used to inventory and describe landform units.

Bennett (1977) proposed a climatic classification scheme for recreation in British Columbia (Appendix III). Climate represents only one parameter of the ELC framework, hence should be considered in conjunction with vegetation, landform, water bodies, animal communities and man.

- 12 -

2.4 <u>Strengths and Weaknesses of Ecological (Biophysical)</u> Classification

Up to this point, discussion has centered on the concept of ELC and its associated ecologically-significant parameters. Why bother with this approach? The following actual or presumed strengths and weaknesses will indicate respectively why some individuals and agencies favour or avoid using the ELC approach. (It should be noted that the stated strengths and weaknesses are generalized and that each project should be evaluated on its own merits.)

The ELC approach has proven useful because:

- 1. The hierarchical framework of the ELC method, its ability to portray the landscape at widely divergent scales and its form of presentation based on the concept of ecological unity makes the ELC approach unparallelled in processing landscape data for planning purposes (Luff and Ojamaa, 1978; Rowe, 1978). ELC has the provision to integrate subsequent, more intensive investigations into previously completed reconnaissance surveys (Gimbarzevsky, 1978b).
- 2. It provides for an holistic overview of the natural environment and often results in the derivation of versatile surveys (Gimbarzevsky, 1978b; Rowe, 1978; Wiken, 1978).
- 3. It emphasizes the documentation of the more stable land characteristics, thus maintaining and enhancing the data bases' utility in the long run.

- 4. It represents one of the most effective uses of remote sensing technology.
- 5. It allows, in theory, for the evaluation and possible improvement upon current or expected land use practices by recognizing and accounting for:
- the thresholds and limits of land ecosystems,
- the range of management strategies available,
- the environmental impact of proposals by indicating the degree of compatibility with the land systems,
- the significance of new technologies,
- the low risk alternatives that are possible,
- the opportunities for renovation and sequential land occupation,
- and, the cost advantages that may be realized over interpretive surveys or comparable number of single disciplinary studies, i.e., less detailed single disciplinary programs often have higher unit costs due to redundancies in the areas of transportation, field work, staff support, cartographic map production and computer data manipulation.

The ELC approach has proven limited because:

- 1. It lacks an agreed upon taxonomic system.
- 2. The costs associated with ELC surveys can be quite formidable. ELC survey costs are related directly to the complexity and size of the area under study, required amount of detail and form of data presentation (Oswald, 1976; Gimbarzevsky, 1978b).

- 3. The time required to undertake ELC surveys may pose a problem as there is often a need for a quick response accompanied by sound decision making, e.g. exploration and development in areas rich in natural resources. Oswald (1976) stated that the biophysical mapping of the Yukon Territories and considerably smaller areas would require a minimum two year period.
- 4. Application of the ELC system can be limited by aircraft scheduling, weather conditions, incidence of forest fires, travel distance among base camps, ground access and other aspects of data collection, manipulation and presentation.

2.5 Methodology for Ecological Inventory and Analysis

The success of ELC studies is dependent on the use of a generally recognized and applied methodological framework. The framework is based on the ability of investigators to inventory, classify and map ecologically significant patterns, thus yielding variously scaled divisions of the landscape (Gimbarzevsky, 1978b; Rowe, 1978). Derivation of representative and understandable taxonomic systems will be dependent on the range of disciplines and interest groups involved in ecological land surveys. If delineated land units are to be meaningful investigators must maintain the dynamic sense of landscape processes and the meaning of spatial patterns. Landscape processes can be interpreted by direct observation or through inference. In areas as vast and unsettled as Canada, a great deal of terrain analysis information has been gathered using inference (Fulton <u>et al</u>, 1974). Inference can be used to determine whether an area has sand, silt or clay surficial parent material through an analysis of the drainage patterns of the area. Inference has been proven effective in assessing soil moisture and fertility, erosion hazard, flood hazard, climate, vegetation condition, slopes, potential land uses and wildlife populations. Use of airphotos and airphoto interpretation, coupled with supportive ground checks, has shown to be invaluable in ELC studies. Airphotos aid in the preliminary field reconnaissance work and mapping of ecologically-significant units, as well as the final compilation and presentation of findings (Lacate, 1969; Rowe, 1978).

Upon reviewing the works of Gimbarzevsky (1978a and 1978b); Gimbarzevsky <u>et al</u> (1978); Lacate (1969); Oswald (1976) and Way (1978) it was found that one overall methodological framework could be used to summarize the ELC approaches proposed by these authors. The data collection and analysis procedures which follow formed the basis of the approach used in the case study portion of this thesis. The following points illustrate the procedures which comprise the aforementioned overall ELC framework:

1. Resource Data Acquisition

a) Preliminary work:

- Gather and review all pertinent information on the area

- 16 -

to be surveyed, paying close attention to information related to bedrock geology, geomorphology, soils, climate, vegetation, land use, hydrology and wildlife communities,

- b) Systematic airphoto analysis:
- Extensive use should be made of remotely sensed date in the form of oblique photographs, large and small scale airphotographs, photo mosaics and satellite imagery,
- The quality, date, scale, and type of aerial photography will have significant influences on the visibility of patterns formed by the key ecological parameters,
- The use of aerial photographs facilitates the observation of landscape patterns that cannot be perceived from ground surveys,
- Prior to going into the field, it is advised that preliminary photo interpretation of the parameters previously mentioned, be undertaken; this will aid in field location and planning the field work,
- Pre-field photo interpretation represents a first approximation of a systematic stratification of the land surface and delineation of ecologically-significant segments of the landscape,
- Pre-field photo interpretation and mapping of patterns of the landscape requires that finite boundaries must often be drawn for conditions that do not actually have finite boundaries, thus resulting in a certain amount

of mapping error at all scales of mapping. Boundary establishment will rely on observed and inferred characteristics of the landscape.

- c) Field verification:
- All ELC studies should include some form of field verification or "ground truthing". Ground truthing is required to add support to the final classification and validity of the survey data.
- As this is usually the most costly phase of ELC studies,
 it is essential that adequate planning and preparation
 take place prior to going into the field.
- Attention should focus on the collection of information relevant to the aspects of land, vegetation, wildlife, hydrology, climate and land use. Information may be kept in the form of field notes, photographs, tape recordings, and field samples of flora, fauna and soil. Rapid field inventories are made possible through the use of standardized forms. An example of one such form is illustrated in Appendix I.
- d) Classification:
- Following a thorough review of all pertinent information, pre-field photo interpretations and field information, the study area is systematically classified and mapped on the basis of landform units and selected ecological parameters, keeping in mind the intensity and purpose of the mapping survey and insuring that the final classi-

fication scheme is readily understandable and useable by resource managers and land use planners. It should be remembered that data collection and analysis procedures should be designed with the anticipated land use(s) in mind.

 At this time, revisions and corrections are made to the preliminary photo interpretations for the area, with boundaries being modified in light of ground truthing information.

2. Resource Data Presentation

- This phase involves the preparation of base maps, transferring of resource details from interpreted aerial photographs to the base for compilation of resource maps and area determination and tabulation by resource classes for inclusion in summary tables. Transference of resource details from interpreted airphotos can be accomplished using a reflecting projector or sketchmaster for low relief areas. For areas with extremes and/or complexity of relief, e.g. the mountainous coastal zone of British Columbia, stereoplotting systems, such as the <u>Radial Kail Line Plotter</u>, the <u>Stereotop</u> or the <u>Bausch and Lomb Zoom Transfer Scope</u>, can be used.

3. Interpretation of Resource Data

- Up to this point attention has been focused on data collection, representation and summation. This phase represents the application of derived findings relating

to the ecological characteristics of the area under study. Resource maps and summary tables are used to present information in condensed, understandable formats.

- To aid management planning and decision making, the kind, location and areal extent of primary ecological resources are often expressed through the use of conventional symbols which indicate the basic characteristics of the delineated map units, i.e., ecologicallysignificant segments of the landscape.
- These ecological characteristics and their associated positive or negative effects on the suitability of the map unit for a particular purpose, may be interpreted from the resource maps and expressed in terms of capability classes for biological productivity or suitability for selected recreational activities or for other uses of interest.
- To aid in planning, land units which have similar uselimitations or suitability ratings for the same anticipated land use(s), are often grouped together into what have been called ecological planning units (Luff and Ojamaa, 1978).

2.6 Summary

Ecological land classification aids in resource planning and management through the recognition of the systematic relationships in the landscape and the impacts of human activities. Its hierarchical framework facilitates the inventory, classification, mapping and interpretation of ecologically-significant features of the landscape. It has proven well suited as a means of conducting integrated surveys of inaccessible areas of Canada, which often lack any previous or systematic resource information. In urban and regional planning, Luff and Ojamaa (1978) stated that the apparent lack of consideration of ecological data in these areas was due to the lack of applicable ecological information and to the limited understanding of the biological and physical sciences by planners. If planners and other resource managers are to meet the needs and aspirations of the public and specific interest groups a sound and generally accepted approach is needed.

3.0 AREA CLASSIFICATION FOR SELECTED RECREATIONAL ACTIVITIES -CLAGUE MOUNTAIN PARK

Attention will now focus on the application of ELC for recreational suitability analysis. The ecological parameters used to establish the recreational suitability within the case study area were landform and parent material, topography, soil moisture regime and drainage, erosion hazard, flood hazard, climate and vegetation. Other parameters that are of importance, but were not used, include soil texture and permeability, stoniness, rockiness, depth to bedrock or impervious layer, frost action and unique site features. Sections 3.4.4 to 3.4.8 and 3.7 of this chapter will present each of these para-

- 21 -

meters and illustrate how they might be used for recreational suitability analysis.

3.1 Case Study

Clague Mountain Park, a small municipal park situated in northwestern British Columbia is the area of interest. This study concentrates on the supply potential of recreational opportunities within the park, with only minimal, indirect references being made to the present and potential future recreational demands on the park. Assessment of the supply of recreational opportunities is limited to the nine previously mentioned recreational activities. This park was chosen because,

- it lacked any form of natural resource inventory that would be of use in future planning and development of the park,
- it is contained within the Municipality of Kitimat and with the increased economic growth currently being experienced in the area it (the park) is forecasted to sustain ever increasing levels of recreational use, hence, warrants attention,
- and, it contains a diversity of landscape types, hence lends itself well to the application of ELC and site suitability analysis.

Although no attempt was made to assess the water bodies and stream courses within the park, the aquatic component of the park plays a vital role in the park's ecological processes, establishment of its physical carrying capacity and aesthetic appeal.

The prime objective of this study is to develop overall suitability ratings of the park for each of the selected recreational activities. These ratings are established on the basis of the site requirements of the activities. One application of this land suitability analysis would be the development of land use policies and general site plans for the park.

3.1.1 Location and Size

Clague Mountain Park forms a part of the Municipality of Kitimat, a small community of approximately 13,000 people situated 645 air Kilometers (400 air miles) northwest of Vancouver, B.C. (Figure 1). The park is found within latitude 54°04' to 54°07' north by longitude 128°41' to 128°47' west. The 1921 hectare (4747 acre) park is situated four kilometers (2.5 miles) northwest of Kitimat (Figures 2 and 3). Access into the east side of the park is by way of a system of interconnecting old and actively used logging roads (Figure 4). At present, access into the Bowbyes Lake area of the park, from the north, is limited, but is forecasted to improve as Eurocan Pulp and Paper Co. Ltd. continues to develop its T.F.L. 40 timber holdings in the vicinity of the Little Wedeene River. Movement within the park is concentrated along a network of rough hiking trails which originate at the parking lot on the

east side of the park. From the parking lot the trails make their way into the subalpine and alpine areas. Access into the park from the east side has been greatly improved with the development of a mining access road. For a comprehensive description of the main trail into Clague Mountain Park, refer to the discussion by Blix (1977) in Appendix IV. As yet, no system of trails has been established in the Bowbyes Lake area of the park (Figure 4).

3.1.2 History and Land Use

Clague Mountain Park was initially leased from the Province of B.C. by the District of Kitimat in August of 1963, pursuant to Lease No. 7318 (Lease Indenture). Annual rental on the lease is \$185.50, subject to review every five years. The lease was last reviewed on August 1, 1978. At the time of establishment, it was declared that the park be preserved and used as a wilderness reserve, providing recreational enjoyment for hikers, skiers, campers and other outdoor enthusiasts (Kitimat District Municipality, 1965). In January of 1965 the Planning Department of the District of Kitimat drafted regulations to control park use with respect to timber cutting, cabin building, disposal of refuse, fire prevention, prohibition of hunting and other activities which may occur within the park (Appendix V).

On July 14, 1969 the Director of Lands, of the then Department of Lands, Forests and Water Resources, Victoria, B.C.,

- 28 -

granted an access road permit to Mr. N. Robak for the purpose of mining exploration within the park. A second party to show interest in the mineral deposits within the park was Bowbyes Mines Ltd. of Prince George, B.C. Both of these operators are no longer active within the confines of the park. The mining activities and associated access road helped to open the park to recreational traffic, both pedestrian and vehicular. Unfortunately, in the process of locating and constructing the access road, environmental damage was done to the soils, vegetation, wildlife habitats and aquatic environments. The access road, which in reality is a rough cat road, follows the contours of the land, seeking out the easiest routes, which often run adjacent to or through streams, through sensitive subalpine meadow environments and up steep slopes composed of materials prone to erosion (Figure 4). As this road forms the major access route into the park, from the east, it is essential that it be upgraded and realigned to facilitate continued, probably increased levels of recreation traffic.

Over the years, the Bowbyes Lakes area of the park has received much attention as a possible site for winter-based recreational activities. On August 26, 1971, Western Resort Planning Service (Burnaby, B.C.) submitted a report to the District of Kitimat stating that, ".... the Clague Mountain-Bowbyes Lake site met all of the major requirements for the establishment of a good ski facility", further it was stated that, "The ski terrain in the proposed area (Clague Mountain-

- 29 -

Bowbye Lake) can more than meet the requirements of any skier whether beginner, intermediate or expert." (Western Resort Planning Service, 1971). Subsequent to the Western Resort Planning Service report, Bruneski (1972) undertook a study of the recreation skiing potential of numerous sites in the Kitimat-Terrace Valley. Bruneski (1972) found that the Claque Mountain-Bowbyes Lake area is too open, i.e., the scattered vegetation provides little in the way of shelter from wind and direct sunlight, especially above the 915 meter (3000 foot) elevation, an avalanche danger exists, most of the skiable terrain is situated on east facing exposures, access into the area would be difficult and costly, and that, generally, the area is not suitable for conventional ski development but has excellent potential for helicopter skiing and ski touring by advanced and expert skiers. Since these two reports presented opposing assessments of the suitability of this area for downhill ski development, it is imperative that before any winter and/or summer-based recreation development is undertaken in this area, a comprehensive inventory, classification and analysis of the natural resource base be undertaken.

In September of 1971 a joint effort on the part of the Aluminum Company of Canada Ltd. and Eurocan Pulp and Paper Co. Ltd. resulted in a feasibility study being undertaken on two proposed routes into the Clague Mountain-Bowbyes Lake area (Philpot and Vrooman, 1971). The purpose of this study was to

- 30 -

establish the optimum route into the Bowbyes Lake recreation area. The major finding of this study was that a proposed route, which would enter the park from the north and run parallel to Bowbyes Creek until it intercepted a section of level ground west of Bowbyes Lake, would be the most feasible and provide the only reasonable access into the proposed ski development area. The other route, which would run from the Service Centre to Bowbyes Lake across the east face of Clague Mountain, was determined to be inappropriate due to problems with excessively steep and broken topography, numerous rock outcrops, two major canyons, hazards associated with falling rock and snow avalanches and the associated high construction and maintenance costs.

The recreation activities presently taking place in the park include, hiking (summer), picnicking and day use (including photography and nature study), limited trail bike and off-road vehicle riding along the "cat trail", primitive wilderness camping (summer and winter), rock climbing, crosscountry skiing, snowshoeing and snowmobiling. With the anticipated future increases in the population of Kitimat and nearby communities, brought on by industrial expansion, establishment of new firms and other regional growth factors, will come increased demands for goods, services, accommodation and recreational opportunities.

As the forest base of Kitimat-Terrace Valley continues to dwindle, as a result of the activities of the local forest

- 31 -

companies, and the availability and cost of fuel for automobiles begin to influence the behavior of both the local and tourist populations, i.e., with increased fuel costs there may be a corresponding decrease in the distance travelled by the individuals to partake in recreational activities, greater pressures will be put on recreational areas adjacent to Kitimat. The close proximity of Clague Mountain Park to Kitimat and the diversity and intensity of outdoor recreational opportunities that are potentially suited to this area warrants the need for sound planning and development if this area is to provide recreational enjoyment to its users in the years to come.

3.2 Landform, Parent Material and Bedrock Geology

Landform is the major framework used for classifying landscapes into ecologically-significant, homogeneous land units. Similar landforms will often exhibit similar textures of surficial parent materials, vegetational complexes and growing conditions and as a consequence, similar landforms within a climatic region will often have similar productive and physical carrying capacities.

The park displays a wide range of landforms and associated parent materials, including fluvial (alluvial), glaciofluvial, organic, colluvial, morainal and exposed bedrock landforms. Five main genetic (landform) categories, i.e., colluvial, fluvial (includes glacio-fluvial), morainal, organic and bedrock, and twenty-three subcategories (landform units) were identified

- 32 -

using the Terrain Classification System approach (Min. of the Envir., 1978).

At lower elevations (30 to 670 meters above sea level) on the east side of the park can be found a large, continuous area of moderately well to well graded accumulations of glaciofluvial sands, gravels and boulders. Fluvial deposits occur adjacent to and southwest of Bowbyes Lake. The fluvial landform deposits were derived from transported materials brought down by mountain streams to areas with low slope gradient southwest of Bowbyes Lake and adjacent to existing and old stream courses within the park. Areas of colluvial deposition can be found throughout the park, with the greatest concentration being in the form of active and inactive talus slopes in the subalpine and alpine areas. Colluvial deposits in these areas are typically non-sorted to poorly sorted with particle sizes ranging from fine clays to massive boulders and blocks of rock. Morainal landforms, in the form of level to steep blankets of rubbly moraine, and till (ground moraine), deposited by valley glaciers, comprise 50% of the total park Generally speaking, the morainal deposits consist of area. well-compacted materials that are usually non-stratified and contain a mixture of particle sizes. In areas of low slope gradient or closed basins, abundance of moisture, prolonged snow cover and vegetation growth characterized by greater rates of accumulation than decay, one is likely to find organic deposits. Areas of the park which contain organic deposits

- 33 -

include the marsh lands adjacent to Bowbyes Lake, the open meadow areas southwest of Bowbyes Lake, the level to hilly subalpine areas which comprise the Main Meadow area and its immediate surroundings and an area situated in the northeast corner of the park, within the Subalpine Mountain Hemlock and Alpine Zones (Figure 5). An extensive area of bedrock, that ranges from being completely bare to being covered with a thin mantle of unconsolidated material, forms the west and south boundary of the park.

As an illustration of the major landform categories and parent material found within the park, the following discussion will deal with a line transect that was "walked" in the field and later plotted in the office. Figure 5 indicates the location of this transect and Figure 6 provides a graphic representation of its side profile. Generally, as one goes from east to west in the park, starting at the parking lot and heading due west towards the summit of Clague Mountain, one would encounter the following landforms:

- 1. a fairly level pitted glacial outwash deposit to a steep glacio-fluvial landform, i.e., using the Terrain Classification System terminology (Appendix VIII) this area is labelled F^Gbs - V, (30 to 600 meters a.s.l.),
- 2. a level to subdued morainal landform, i.e., M^Im H, dotted with kettles, small ponds and accumulations of organic soils (600 to 690 meters a.s.l.),

- 34 -

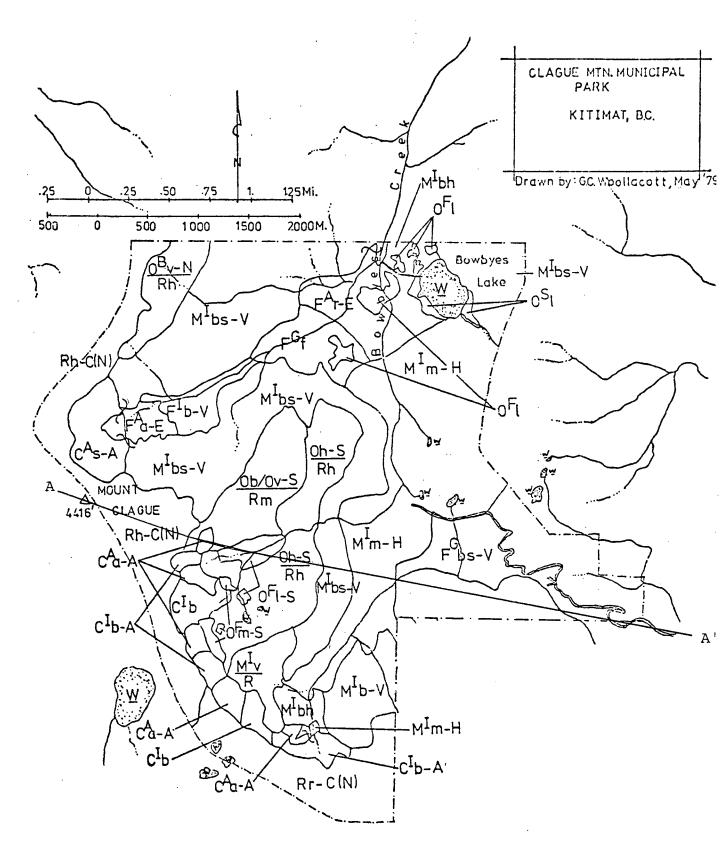

Fig.5. Terrain Units of Clague Mountain Park. A-A' line transect illustrated in Figure 6.

- 35 -

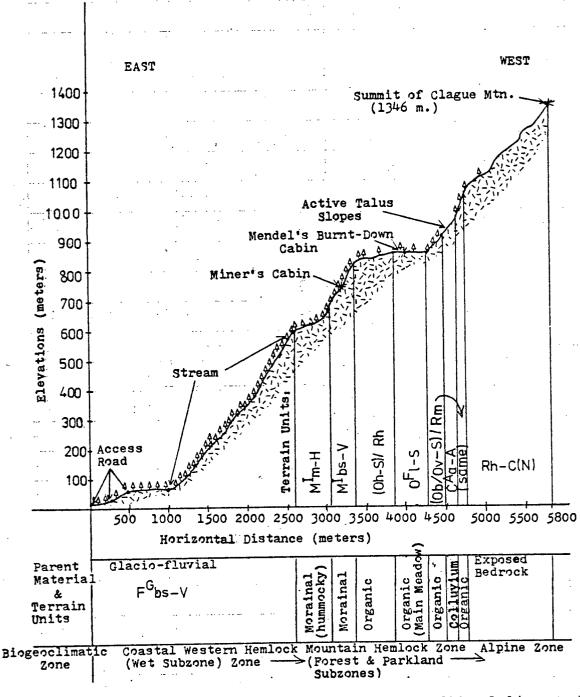

Fig.6. Graphic illustration of profile delineated by A-A' line transect of Clague Mountain Park, Kitimat, B.C.

- 36 -

- 3. a steep, extensively eroded and heavily treed morainal landform, i.e., M^Ibs - V (690 to 820 meters a.s.l.),
- 4. three organic landform types, i.e., $\frac{Oh S}{Rh}$, $o^{F_1} S$ and $\frac{Ob/Ov S}{Rm}$, that are, typically, level, subdued or hummocky over fine textured colluvium or fluvial material and serve to mask the underlying bedrock (820 to 1050 meters a.s.l.),
- 5. a narrow zone (150 to 200 meters wide) of active colluvial slopes (talus and rockfall areas), i.e. C^Aa A (920 to 975 meters a.s.l.),
- 6. and, finally, an area of extensive exposed bedrock and bedrock covered by a thin mantle of unconsolidated material, i.e., this area is labelled as Rh - C(N) and ranges from approximately 1050 to 1346 meters a.s.l. This area is a typical "krummholz" landscape, being inhabited by scattered clumps of low lying alpine heathers, lupines and grasses, as well as dwarf yellow cedar, amabilis fir and common juniper.

The characteristic bedrock of Clague Mountain Park and surrounding region consists of igneous intrusive granitic (chiefly granodiorite and quartz diorite) rock with minor gneiss and schist (Ryder, 1978). The bedrock type is relatively resistent to weathering, resulting in slopes that are generally steep and terrain that is quite rugged. Physical weathering disintegrates this rock type into extremely coarse rubble on colluvial slope (talus) and large boulders in till deposits. Chemical weathering of the olivine, pyroxene, augite, hornblende, biotite and calcic feldspar minerals of granitic bedrock yields granular, gritty residues composed of mixtures of quartz, potash and sodic feldspar crystals. These residues form a major portion of the sandy, gritty tills and sandy outwash deposits that are often found in areas of igneous intrusive granitic bedrock.

3.3 Topography

The structural characteristics and relief of landforms are used to describe what is commonly called "topography". Hills, knolls, plateaus, flats, depressions, troughs, scarps and rolling terrain are some of theterms used to describe the collective effect of the physical features of the landscape. The Terrain Classification System developed for B.C. makes use of "surface expressions" to denote topographic relief, where the surface expression of genetic materials (parent materials) is their form (assembly of slopes) and pattern of forms (Min. of the Envir., 1978).

Slope measures the extent to which a surface varies from the horizontal and is usually expressed in percent or degrees. Measurements of slope can be made in the field with the aid of instruments such as the <u>Abney</u> or <u>Suunto</u>, while in the office, slope estimates can be made using existing topographic maps. Slope greatly affects all forms of recreation. With increased slope there is an increased potential for both surface erosion

- 38 -

and mass soil movement (Swanston and Dyrness, 1973; Hawes, 1974). With increased slope there is usually a corresponding increase in site preparation, facility construction and subsequent maintenance costs. Generally, in terms of surface erosion, slopes less than five percent have few limitations whereas slopes greater than 30 percent have severe limitations. In the context of mass soil movement, slopes less than 30 percent have a few limitations whereas slopes greater than 30 percent have a greater degree of limitation (Hawes, 1974). Vold (1975) found that steep slopes posed major limitations for both trails and camp grounds. Slopes greater than 60 percent (30 degrees) will prove to be severely limiting for almost all recreational uses and developments. Conversely, mountaineering (rock climbing), downhill skiing, wilderness hiking and viewing of scenic areas require steeply sloping terrain if the recreational pursuit is to be both personally gratifying and technically feasible (Montgomery and Edminster, 1966; Min. of the Envir., 1976).

Aspect refers to the orientation of a body or surface and it is usually described as being level, north, northeast, east, southeast, south, southwest, west or northwest facing basedon compass measurements. The range of aspects can have profound influences on what types and levels of activities will occur in an area. Campgrounds and picnic areas require the drier, warmer weather and maximum sun exposure afforded by south facing and level exposures, but should avoid areas of

- 39 -

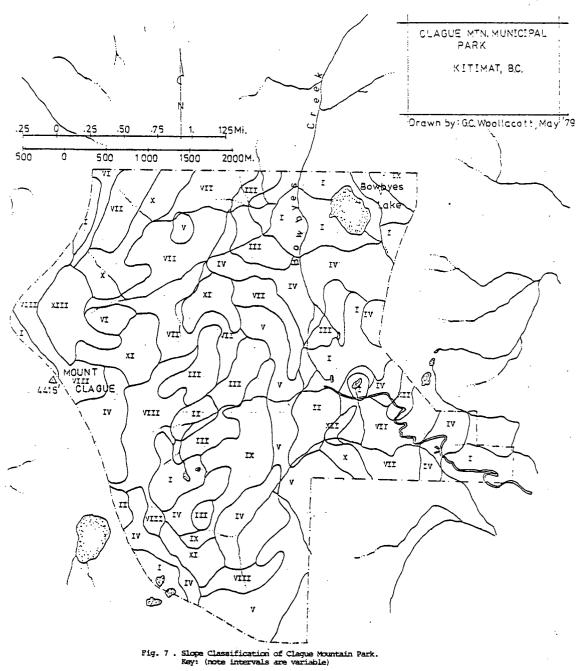

long snow duration, higher moisture retention and cooler temperatures, typical of north facing exposures. Conversely, for winter sports such as downhill skiing, north facing exposures are favoured, except for areas with extreme cold conditions, whereas, southwest facing slopes, with characteristically high rates of snow deterioration should be avoided.

Using existing topographic maps and field experience, Clague Mountain Park was classified into 13 slope classes and eight aspect classes, as shown in Figures 7 and 8, respectively. Selection of slope class ranges was governed by the site requirements of the nine selected recreational activities.

3.4 Soils

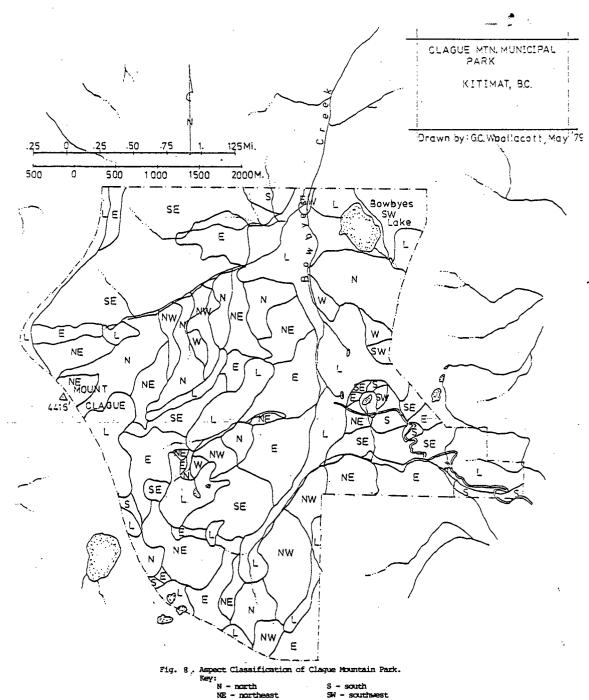

Soil characteristics aid in the selection of potential recreational sites. The suitability of soil for recreational activities can be established using the following soilsrelated properties: moisture, drainage, texture, permeability, stoniness, rockiness, depth to bedrock or impervious layer, frost action, erosion potential, flood potential and soil taxonomic grouping (Montgomery and Edminster, 1966; Stevens, 1966; James, 1973; Hawes, 1974; Vold, 1975; Eekman, 1976; Jubenville, 1976; Min. of the Envir., 1976). These properties can be determined using physical measurement, chemical analysis and through direct observation and inference. As an example, erosion potential can be inferred from slope, landform, soil texture, parent materials, soil porosity, meterological factors

- 40 -

| welt. (whole might data are variable) | | | |
|---------------------------------------|------|---------|--|
| I 0-5% | VIII | 41-50% | |

| VII 36-40% | | | |

- 41 -

NE - northea E - east SE - southea L - level ust S - south SW - southwest W - west NW - northwest

and plant and litter cover. Flood potential can be determined using existing drainage patterns, meterological information, landform characteristics and the condition of vegetation adjacent to water courses.

No detailed soils inventory and mapping has been done for Clague Mountain Park. Due to constraints arising from the lack of existing information, time and monies, as well as the limited expertise of the author in the area of soils identification, classification and analysis, no attempt was made to undertake an extensive study of the soil landscapes found within the park. Knowledge of soils and soils characteristics is one of the most important elements to consider in the selection of potential areas for new site development and in the management of existing sites. It is recommended that prior to the establishment of new facilities or upgrading of existing structures, trails and roads within the park, that a comprehensive study of the park's soils be undertaken. For the purpose of this study, only three soils-related parameters were used to aid in the establishment of the recreational suitability of the delineated landform units, these being, erosion hazard potential, flood hazard potential and soil moisture regime.

Although not a steadfast rule, in general, different landforms and associated parent materials are characterized by different soils types that have developed as a result of unique combinations of pedogenic processes operating within and characteristic of each landform. In Appendix II the charac-

- 43 -

teristic Soil Orders, Great Groups and parent materials of the Coastal Western Hemlock, Mountain Hemlock and Alpine Biogeoclimatic Zones are indicated. The aforementioned zones are all found within Clague Mountain Park (Figures 6 and 13).

3.4.1 Soil Moisture Regime and Drainage

Soil moisture or hygrotope classes refer to the moisture regimes of soil during snow-free periods and not following snowmelt, prolonged rainy or dry periods. The moisture regime of the soil is a combination of the local climate and internal and external drainage. Within a climatic region soil drainage is controlled by the texture of surface material and depth to the underlying bedrock. External drainage is a function of topography, texture and vegetation. Two other deterministic factors are slope and aspect, because they control the drying power of the air (Gimbarzevsky, 1964).

Soil drainage is probably the most important soil property affecting the suitability of a soil for recreation use (Vold, 1975). Soils that are wet for a majority of the year pose severe limitations for campsites, recreational roads and trails, picnic grounds and other intensive use areas. Dry soils can prove limiting due to an inability to establish and maintain suitable vegetative cover, dust problems and difficulties associated with vehicular movement in these soils (Montgomery and Edminster, 1966; Eekman, 1976). Soil moisture regimes can be inferred from soil drainage properties,

- 44 -

topographic relief, parent material and seepage and/or ponding on the soil surface. The categories used to describe the soil moisture regimes are as follows:

- a) Very dry to dry (very xeric to xeric) knolls and peaks of rocky outcrops or lithic (ranker-like) soils of convex relief on ridge crests. Soils are shallow and well drained.
- b) Moderately dry (moderately xeric) well drained soils on convex relief of upper slopes or stony glacial tills of convex or straight relief. Seepage absent during snow-free periods.
- c) Mesic medium textured (loamy) soils of straight to shallow convex relief. Soils have good drainage and seepage is absent or rarely present. If present, seepage is deep in the profile and occurs only during the snowfree periods.
- d) Hygric moderate to imperfectly drained soils of straight to concave relief. Gleying is evident in the soil profile and seepage water is usually present. The maximum water level in soil may be at or near the soil surface for part of the snow-free period.
- e) Hydric soils with imperfect to very poor drainage.
 Soils are saturated or inundated for most of the year.
 Concave or straight relief usually on lower slopes,
 spring-water swamps, stream edges and moors. (Brooke
 et al, 1970).

Soil drainage is the rate of removal of water from soils in relation to additions. It is affected by a number of factors, including texture, structure, slope gradient, length of slope, water holding capacity, soil permeability and evapotranspiration. Rapidly to moderately well drained soils have few limitations for recreation activities and associated facilities, while poorly drained and very poorly drained soils have significantly greater limitations (Hawes, 1974; Min. of the Envir., 1976). Imperfectly drained soils present a greater limitation for intensive recreational use than for extensive use, e.g. family campgrounds versus wilderness hiking trails.

Gross drainage pattern is an important identifier of landforms and provides valuable insight into the suitability of an area for various recreational activities (Way, 1978). Analysis of the general physiography and drainage patterns of rivers, creeks and gullies will provide insight into the underlying bedrock, type of surface and sub-surface materials, textures and landforms characteristic of an area. The following soil drainage classes are useful for classifying the internal and external drainage characteristics of soils: very rapidly drained, rapidly drained, well drained, moderately well drained, imperfectly drained, poorly drained and very poorly drained (Agric. Can., 1978).

Clague Mountain Park is located within the Kitimat Ranges of the Coast Mountains of British Columbia (Figure 9). The Kitimat Ranges are comprised of granitic mountains which

- 46 -

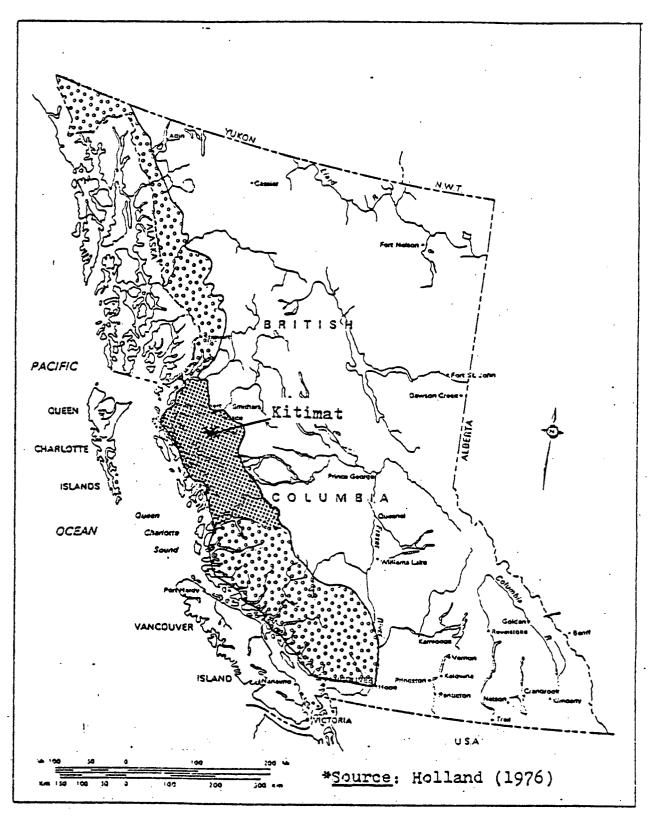

Fig.9. Physiographic subdivisions of British Columbia.

Coast Mountains

Kitimat Ranges (within Coast Mountains)

47 -

extend from the Nass River in the North to Burke Channel and the Bella Coola River in the south (Holland, 1976). Mountains within these ranges are characterized by heavily eroded granitic rock of the Coast Intrusives, with the rather bold, massive mountains of monolithic granite being common features of these ranges. Mountain peaks within the Kitimat Ranges are between 1980 and 2300 meters (6500 and 7500 feet) in height, being, characteristically, round-topped and dome-like in appearance.

Glaciation of this area has resulted in rounded ridges and summits of all but a few of the highest mountains, as well as wide spread deposits of glacio-fluvial material in the valley bottoms and on higher elevation benches. One rather unique feature of the western margin of the Kitimat Ranges is that cirque erosion often reached sea-level. The Kitimat Ranges are characterized by a spectacular system of fiords which developed as a result of intensive glaciation of British Columbia's mountainous coastline. These ranges have significantly fewer glaciers than those to the north and south, with no extensive icefields remaining. Within the park, permanent snowpacks exist in the form of rather limited accumulations of snow which can be found in sheltered gullies and on north facing slopes.

The major drainages which dissect the Kitimat Ranges are aligned and flow in an east to west direction. Runoff from the park flows into the Kitimat River system by way of the

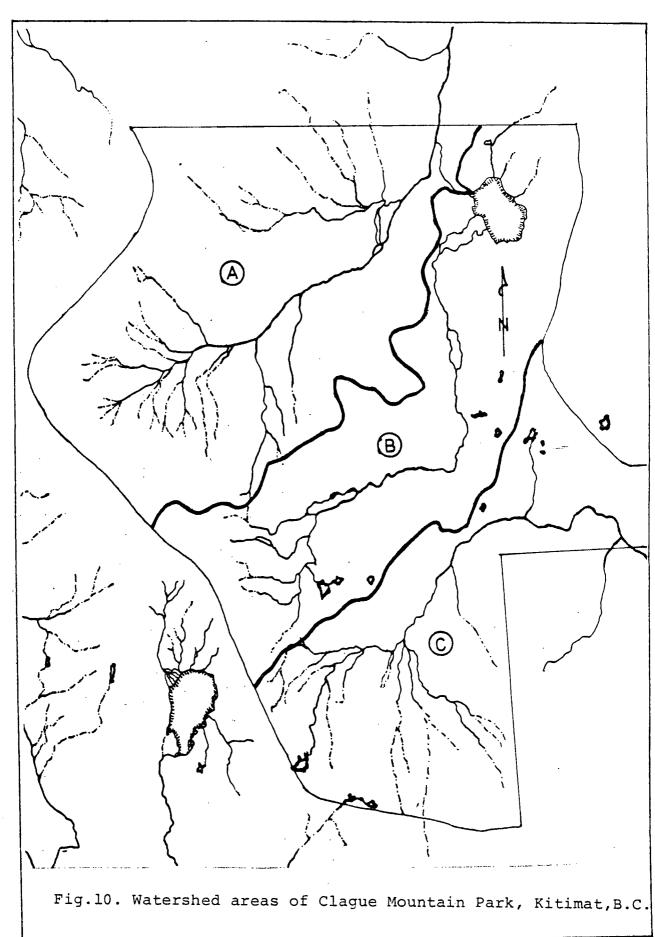

- 48 -

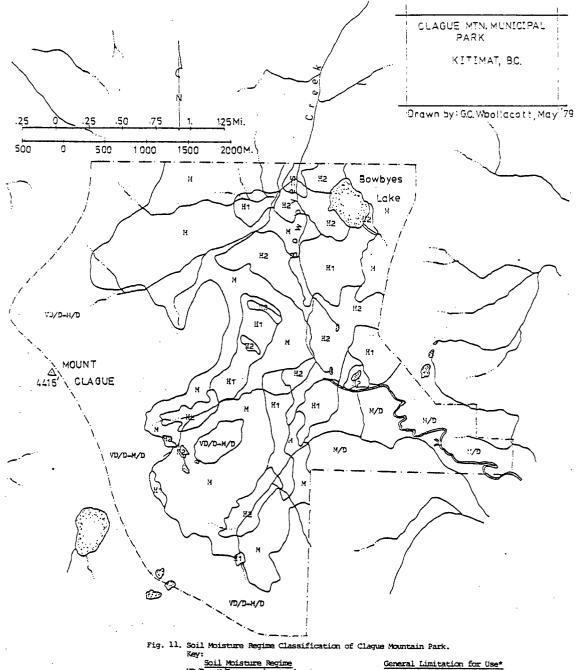

Little Wedeene River to the north (of the park) as well as streams which flow to the east and south of the park. Bowbyes Lake is the major catchment within the park with lesser ponds and higher elevation tarns being evident. On the basis of photo interpretive work done by the author, Clague Mountain Park was divided into three rather distinct watershed areas (Figure 10). Runoff from watershed areas "A" and "B" flows into the Little Wedeene River by way of Bowbyes Creek, and, subsequently, into the Kitimat River. Watershed area "C" drains into the Kitimat River by way of an, as yet, unnamed stream which flows eastward, paralleling the main trail into Clague Mountain Park.

The usual heavy snowfalls and high levels of precipitation occurring throughout the year in this area, results in active year-round stream flows. During the spring melt, ephemeral streams become bubbling freshets which overflow their banks, flooding streamside areas and level marshlands found within the park. The rapid runoff and high flow volumes result in extensive reworking of both the glacio-fluvial and glacial till deposits found within the park, leading to deep gully formation and the transport of large volumes of material.

Based on ground reconnaissance and airphoto interpretation Clague Mountain Park was classified into five soil moisture regime categories (Figure 11).

- 49 -

| Soil Moisture Regime | General Limitation for |
|--|------------------------|
| VD/D - M/D: very dry to dry to moderately dry M/D : moderately dry | None to Slight |
| M : mesic Hl : hygric H2 : hydric | Severe |
| * Recreational uses. | |

- 51 -

3.4.2 Erosion Hazard

Erosion is the wearing away of soil or rock through the actions of running water, wind, ice, gravity and other geological processes. The criteria used to establish the erosion potential of an area are slope and landform (length of slope and topographic relief), parent material, soil texture, soil porosity, meterological factors (form, amount and duration of precipitation), and soil compaction properties (as influenced by soil texture and moisture content) (Swanston and Dyrness, 1973). With increased slope there is an increase in erosion potential. Parent materials high in quartz, e.g. granite, quartz diorite, granodiorite and high quartz sandstones, develop into soils which have high erosion potential. Soils derived from basalt, andesite or gabbro have low erosion potential.

A major deterrent to surface erosion is the presence of an adequate plant and litter cover. It is of prime importance that site planning and development allows for the continued establishment and growth of both natural and man-induced vegetational communities (Densmore and Dahlstrand, 1965; Stevens, 1966; Rothwell, 1971; Swanston and Dyrness, 1973).

Erosion patterns, density of occurrence and steepness of gradient will indicate the cohesiveness of soils and the texture of surficial deposits. Gully analysis has shown to be useful for identifying landforms, slope profiles, soil textural classes and soil drainage characteristics. In general, U-shaped gullies form on silts, sands and sandy clays, V-shaped

- 52 -

gullies are indicative of granular materials (course, clean sands and gravels), and wide, soft-bottomed or broad-shaped gullies develop in semi-plastic or plastic materials high in clays. Table 1 would prove useful for establishing the overall suitability of an area for a range of recreational activities.

Table 1. Guide for Assessing Soil Erosion Hazard¹

¹ Source: Vold (1976) in "Biophysical Soil Resources and Land Evaluation of the Northeast Coal Study Area (B.C.): 1976-77: Vol. I.

² Erosion by rivers and streams on floodplains is not evaluated here.

Table 1 was used to establish the erosion hazard ratings of the delineated landform units within Clague Mountain Park. The ratings are given in Table 14: Ecological (Biophysical) Characteristics of Landform Units, of Section 4.0.

3.4.3 Flood Hazard

Flooding can result from high levels of precipitation, rapid snowmelt, failure of man-made retaining structures, removal of extensive areas of forest cover through natural causes and/or the activities of man. Flood hazard ratings of areas pertain to the normal "season of use", e.g. from late November to the end of April for downhill skiing in the southwestern part of B.C. Establishment of flood hazard ratings is complicated by the current move towards "all seasons" recreational developments. The degree of flooding can be described as being none, rare, occasional or frequent (Griffin, 1977). Areas subject to no or rare flooding have a none-slight to moderate limitation for most recreational activities and associated facilities. Rare flooding implies the occurrence of inundation sometime over a period of several years. Areas susceptible to seasonal flooding (regular occurrence) or subject to occasional or frequent flooding are ranked as having moderate to severe limitations depending on the activity and its specific site requirements.

Sites with moderate flooding limitations are unsuitable for permanent development such as campgrounds with buildings,

- 54 -

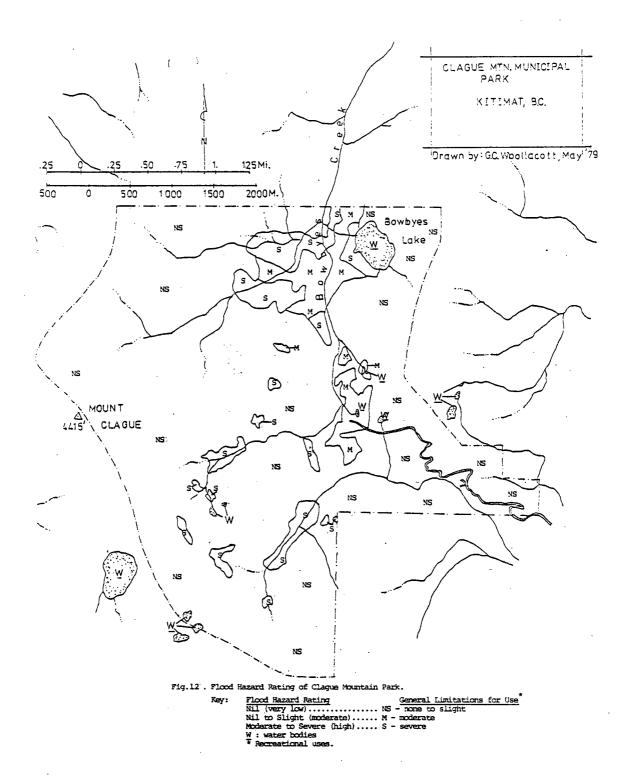

tables, roads, camp pads and other facilities susceptible to flood damage (Hawes, 1974). The use of wells and on-site sewage disposal systems would be limited in areas susceptible to occasional or frequent flooding. Areas subject to frequent flooding (3 to 4 times) during season of use or flooding occurring in response to limited rainstorms would be unsuitable for intensive use and suitable for extensive use only during the drier periods of the year (Min. of the Envir., 1976).

Based on ground reconnaissance and airphoto interpretation Clague Mountain Park was delineated into areas of none to slight, moderate and severe flood potential (Figure 12).

3.4.4 Texture and Permeability

Soil texture refers to the relative proportions of soil separates, i.e., sands (2.00 to .05 mm in diameter), silts (.05 to .002 mm in diameter) and clays (less than .002 mm in diameter). Texture is related to such soil characteristics as drainage, permeability, cohesion, erodibility, compactability and nutrient availability. These soil characteristics influence vegetative productivity and affect the amount and type of recreation use that may occur in a given area. Soils high in clay become sticky when moist and require long drying times after wetting. Soils that are composed of loose sands can prove to be undesirable as they are often unstable when dry. The last point illustrates the concepts of permeability, which is a measure of the ability of soil to transmit water and air, and cohesion, which is the ability of soil to stick together.

- 55 -

- 56 -

Permeability measures the rate at which gases or liquids pass through or penetrate the soil. It is dependent on texture, cohesion, compaction, existence of impervious layers, soil structure, moisture condition of soil profiles and horizon porosity. Soils which are high in clay have low permeability but high cohesiveness, making them subject to puddling and compaction when wet, thus causing drainage restrictions.

Soils high in sand are highly permeable but quite unstable when dry. Deficiencies in soil nutrients and/or moisture levels often restrict the use of these soils. Sandy soils tend to be highly erodable and dusty when dry. Sandy loam and loam textured soils are permeable with good cohesive properties which result in few textural limitations. These soils exhibit only slight limitations for most intensive and extensive recreational activities.

3.4.5 Stoniness

Stoniness refers to the proportion of stones in or on the soil's surface, expressed as the percentage of land surface or soil profile occupied by stones or rock fragments coarser than 15 cm (6 in) in diameter (Agric. Can., 1978). Cobbles, flags, boulders and all other types of stones in excess of this maximum size limit are called "course fragments". Montgomery and Edminster (1966) considered all stones or rock fragments in excess of 25.4 cm (10 in) in diameter as being course fragments. The range of stoniness classes is from non-stony ("no

- 57 -

modification" under the U.S.D.A. system of classification) to excessively stony ("stony-rubble land" under the U.S.D.A. classification system), or from less than .01 to 50.00% and greater of the total surface or soil profile, respectively, being occupied by stones greater than 15 cm (6 in) in diameter (U.S.D.A., 1951; Montgomery and Edminster, 1966; Agric. Can., 1978). Increasing restrictions on the type and intensity of recreational use will occur as the size and/or density of soil fragments increase. As the content of stones increases a corresponding increase in the costs associated with site preparation and the installation and maintenance of facilities will result. Soils that are exceedingly or excessively stony are considered to have severe limitations for use (Agric. Can., 1978).

A moderately coarse fragment limitation (50 to 75% by volume) would seriously limit intensive development and pose only minimal problems for extensive recreational activities, e.g. hiking and wilderness camping. Where the coarse fragment represents over 75% of the total soil surface or profile, virtually all intensive recreational activities would be prohibited (Min. of the Envir., 1976).

3.4.6 Rockiness

Rockiness refers to that portion of the land's surface which consists of exposed bedrock, rock outcrops or patches of thin soil over bedrock. Rockiness classes range from non-

- 58 -

rocky ("no midification" under the U.S.D.A. system of classification) to excessively rocky ("rock outcrop" under the U.S.D.A. system of classification). The exposed bedrock defined by these classes range from less than 2 to 90% and greater of the surface area, respectively (U.S.D.A., 1951; Montgomery and Edminster, 1966; Agric. Can., 1978). Bedrock poses severe limitations for most recreational activities requiring site preparation and facility development and maintenance. Septic tank facilities, water and electrical services, foundation construction, road building and many other site development activities will be prohibited in areas of excessive bedrock. The combined influence of exposed bedrock on steep slopes eliminates most intensive and extensive recreational activities.

3.4.7 Depth to Bedrock or Impervious Layer

Shallow soils over bedrock or impervious layers will have varying degrees of limitation depending on the extent and type of required site development. Concern for depth to bedrock or impervious layer is vital when planning for buildings, septic tank filter fields, road locations, camping and picnic areas, paths and hiking trails and intensive play areas (Min. of the Envir., 1976). Soils less than 1 meter (3 feet) deep will pose severe limitations for buildings and soils less than .6 meters (2 feet) deep will have severe limitations for play areas (intensive use) (Montgomery and Edminster, 1966). Allowance should be made for the affects of other factors such

- 59 -

as frost heave, piping, soil texture classes, bearing capacities, slope and internal and external drainage and moisture regime. Poor soil drainage can prohibit construction of onsite sewage disposal facilities. Shallow soils will limit the rooting depth of plants and hinder the establishment and maintenance of vegetation cover due to a decreased soil moisture holding capacity and higher levels of soil erosion.

3.4.8 Frost Action

The heaving of soil subgrades due to the formation of ice lenses and the subsequent loss of stability on thawing is known as frost action (U.S. Dept. of the Interior, 1974). The severity of frost action will depend on the type of soil, availability of a source of water and time rate of fluctuation of temperature about the freezing point. Fine-textured loams and silts are particularly susceptible to frost action due to their inherent capillarity and perviousness. Soil particles that are brought to the surface by frost action are susceptible to erosion by wind, water and/or gravity.

In an attempt to classify frost action, the Resource Analysis Branch (Victoria, B.C.) established a frost action rating system based on modifications to existing U.S.D.A. Soil Conservation Service (U.S.D.A., 1971) guidelines (Table 2: Vold, 1977). Under this system soil is ranked as being of low, moderate or high frost action on the basis of soil texture. Texture will have a significant influence on the extent to

- 60 -

which frost action will occur in soils. The proposed system is shown in Table 2:

Table 2: Frost Action Classification by Soil Texture Classes

| Frost | Action | Class |
|-------|--------|-------|
|-------|--------|-------|

| | Low | Moderate | High |
|------------------------------|------------------------------|--------------|-----------------|
| | GW, GP ³ , GW-GM, | | ML, MH, OL, OH, |
| Soil Classes ² | GP-GM, SW, SP, | & SM (medium | CL & SM (fine |
| | SW-SM, & SP-SM | sands) | sands) |

- ¹ Source: Vold (1977).
- ² Definitions and potential frost action ratings for major third level divisions of the Unified Soil Classification System are contained in Appendix IX.
- ³ These soils are rated as high in the Alpine Zone or Subalpine Krummholz Subzone, or when imperfectly to poorly drained.
- ⁴ These soils are rated as moderate in the Alpine Zone or Subalpine Krummholz Subzone.

In alpine and subalpine zones three types of frost action have been recognized (Ryder, 1976). Frost shattering is the process whereby bedrock or rock fragments are split and broken due to the expansion pressures of freezing pore water and water in fractures. The intensity of frost shattering is dependent on the amount of available moisture, nature of rock material, the number of frost (freeze-thaw) cycles and the freezing rate. Blockfields, mountain top detritus (till mantle), block slopes, block streams, rock glaciers and talus slopes develop when frost shattered debris creeps, flows and/or falls down slope. Frost heaving is the upward displacement of objects (soil particles and rock fragments) resulting from pressures generated by freezing water. Frost heaving usually occurs when there is an abundance of moisture in the soil substrate, a gradual fall of temperature leading to a slow descent of the freezing point, and soil or surficial material of silt or silt loam texture. The third type of frost action is known as frost sorting. The "patterned" ground characteristic of frost sorting, consist of circles, polygons, and nets on horizontal or gently sloping ground and steps and strips on moderately sloping surfaces.

3.5 Vegetation

In areas of recreational use, be it intensive or extensive, the vegetation component should be included in site planning and development. The ability of a site to support different types and intensities of recreational use is governed by the capacity of soils to establish and maintain vegetative cover. As an example, the low lying, slow growing plants of high elevation alpine meadows are quite susceptible to damage resulting from trampling and campsite establishment. Conversely, the protection and enhancement of vegetative ground cover facilitates the prevention and control of erosion, which could lead to soil and general site degradation (Densmore and Dahl-

- 62 -

strand, 1965; Montgomery and Edminster, 1966; Stevens, 1966). Plant communities perform vital roles in biogeochemical (Nutrient) and water cycling (Lautenbach <u>et al</u>, 1974). Trees and other ground cover contribute to the visual enjoyment and scenic integrity of natural resources, provide shelter from direct sunlight, high winds, drifting snow and other climatic factors, help to attenuate noise by absorbing and reflecting sound, provide a sense of privacy by screening out the views, sounds and smells of other users, perform a vital role as habitat for wildlife populations (permanent and seasonal) and help to prevent or diminish the effects of rock slides, snow avalanches and other naturally occurring or man-induced phenomena.

The suitability of vegetation for recreational activities can be established on the basis of sensitivity, resilency, density, height and vegetation type (including hazard and nuisance categories) (Murray <u>et al</u>, 1971; Burden and Randerson, 1972; Hawes, 1974; Eekman, 1976; Min. of the Envir., 1976; Alberta Rec. & Parks, 1979).

3.5.1 Vegetation Parameters Used to Assess Recreation Capability

Sensitivity is the ability of vegetation to withstand various intensities and types of recreational uses. Recognizing that the degree of sensitivity varies from species to species, what is of greater concern is the ability of each vegetation

- 63 -

type to recover from or re-establish after destructive use. The process of recovery or re-establishment is described in terms of community succession. As an example, in alpine and subalpine environments the rate of succession is low, particularly where soils are shallow or unstable. The short growing season, harsh climate, limited time available for plants to complete their life cycles and the fragile nature of vegetation communities, make certain areas of the subalpine and alpine environments highly vulnerable to irreversible destruction by man (Lautenbach et al, 1974; Eekman, 1976). Physical damage to vegetation cover will often lead to the establishment of resistent and often less spectacular weedy species at the expense of more susceptible (fragile) flowering plant species (Corns, 1976; Eekman, 1976). Vegetation that is frozen, brittle and not protected by snow or adjacent vegetation will suffer irreversible damage if it is crushed by man, whether on foot or through the use of all-terrain vehicles.

Vegetation density is the percent cover or number per given area of individual vegetation types, i.e., species or vegetation strata. Vegetation density will have a very direct bearing on the intensity and type of recreational activity that can occur in an area as well as the costs of site preparation. Insufficient vegetation can pose a problem where vegetation is required for screening users from one another or where users require shelter from direct sunlight, high winds or other climatic factors.

- 64 -

Vegetation height generally refers to the vegetation strata, be it understory shrub vegetation or the overstory canopy. Of concern to recreationists is the height of vegetation overhang or clearance under the vegetation. Both the overall height and height to overhang are of importance as they influence the type and intensity of recreational pursuits. Vegetation with low overhang will pose varying degrees of limitation depending on the specific minimum clearance requirements of given activities. As with vegetation density, the height of vegetation will influence the degree to which snow accumulates, which, in turn, will dictate the type, intensity and duration of winter-based recreational activities.

Areas characterized by a large variety of plant species are often better suited for aesthetic appreciation and nature studies (Hawes, 1974). In recreation site planning and development it is essential that hazard and nuisance vegetation species are accounted for. Species such as devil's club, poison ivy, stinging nettle, salmonberry, gooseberry and rose can be both a hazard and a nuisance. Mosses and other turfy vegetation will pose moderate to severe limitations for mountain climbing, as exposed, dry bedrock is essential for safe climbing. In areas planned for intensive use camping and picnicking, an abundance of nuisance and/or hazardous vegetation will increase the costs of site preparation and maintenance, and may prove to be a source of ongoing aggravation following site development. The site requirements of

- 65 -

recreational activities and the period of activity (spring, summer, fall and/or winter) should be considered when assessing an area for nuisance and/or hazardous vegetation.

Based on studies done by Jarvinen and Schmid (1971), Masyk (1973), and Wanek (1971) it was found that snowmobiling is or can;

- a) be a major cause of damage to shrubs, saplings and other vegetation adjacent to designated snowmobile trails, as well as in areas of uncontrolled use,
- b) result in decreased soil temperatures as a result of snow compaction and subsequent deep freezing, which in turn can seriously affect the survival of soil microbes and subnivean plant and animal communities,
- c) be blamed for incidences of wildlife harassment, littering, and air and noise pollution, which in turn can significantly decrease the opportunities for others to enjoy a given area,
- d) result in alterations to alpine meadow habitats so that certain animal and plant species normally found in these areas may be destroyed or forced to migrate to other areas,
- e) and, result in extensive site degradation arising from intensive use of steep slopes, use of areas with southern exposures and use of trails too early or too late in the season, when snow cover is inadequate.

- 66 -

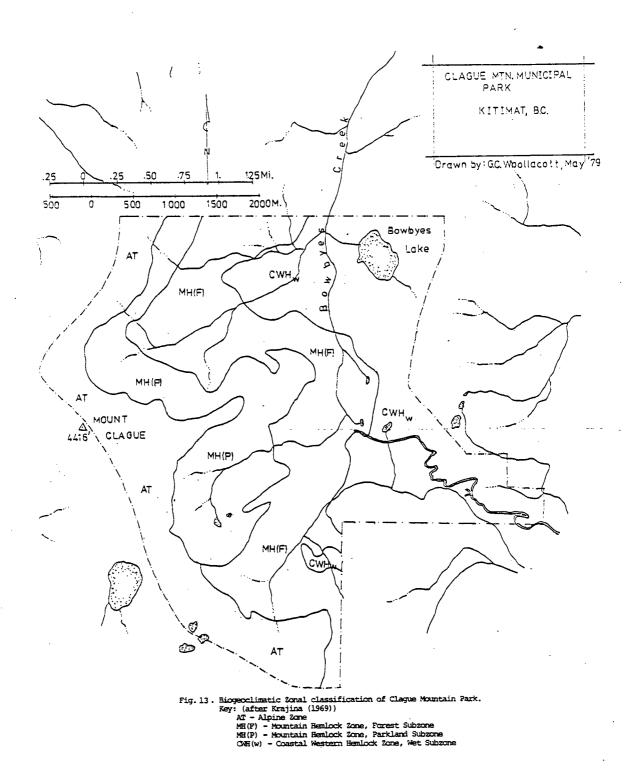

3.5.2 Recreation Suitability Rating Using Biogeoclimatic Zones

Eekman (1976) presented an approach which used Biogeoclimatic Zones (Krajina, 1969) to establish recreation suitability ratings. Under this approach plant associations are assigned recreation suitability ratings on the basis of somewhat subjective assessments of vegetation sensitivity, resilency (recovery and re-establishment of damage plants), density, height and type and the site factors of hygrotype, drainage, snow duration, ground water depth, seepage characteristics, slope, permeable soil depth, thickness of humus layer and stoniness of soil profile.

The three Biogeoclimatic Zones used to assess recreational suitability within Clague Mountain Park were the Coastal Western Hemlock Zone (CWH with Wet Subzone), the Mountain Hemlock Zone (MH with Parkland and Forest Subzones) and the Alpine Zone (AT). Figure 13 shows the spatial extent of these zones within the park. Appendix II contains descriptions of each of the aforementioned zones, followed by summaries of the characteristic species of each of the plant associations of each zone and generalized suitability ratings of these associations for the set of selected recreational activities.

Not all of the plant associations for each zone are found within the park. The characteristic plant associations of the Coastal Western Hemlock Zone (Wet Subzone) include Tsugo-Strutheopteretum spicant, Lysichito-Vaccinietum

· **-** 67 **-**

- 68 -

<u>alaskaense</u>, <u>Thyjo-Oplopanicetum horridus</u>, and <u>Populo-</u> <u>Loniceretum involucratae</u>; of the Mountain Hemlock Zone (Forest Subzone) include all those indicated in Appendix II; of the Mountain Hemlock Zone (Parkland Subzone) include all those indicated in Appendix II except the <u>Vaccinio-Tsugetum</u> <u>mertensianae</u> plant association; and of the Alpine Zone include all those indicated in Appendix II. Refer to Appendix VI for photographs showing some of the common vascular plants and shrubs found within Clague Mountain Park.

3.6 Climate

Climate plays a key role in the selection of recreation areas and the types and intensities of recreational activity pursued in these areas. Climatic parameters such as temperature, wind, duration of sunshine and precipitation will aid in determining the suitability ratings for an area as well as having a direct influence on the capacity of an area to attract and sustain recreational activities (Bennett, 1977). The specific climatic or meterological factors that are considered important for establishing the carrying capacity and suitability rating of an area for various recreational activities are listed in Table 3:

Given that climatic factors will affect people differently, which ones can be used to inventory, classify and rank areas as to their suitability for recreational use? Bennett (1977) selected temperature, precipitation, sunshine (solar

- 69 -

Table 3. Recreation Activity-Related Climatic Factors¹

- 1. Precipitation amount (mean annual, mean monthly and mode), form, duration (mean number of precipitation days), pattern (distribution), snow depth, snow quality and snow season.
- 2. Temperature mean annual and monthly, daily highs and lows, monthly record of extreme or record of daily highs and lows, mean length of frostfree period, average start and finish dates and degree hours that are frostfree.
- .3. Wind mean wind velocity and direction by day and month, record of extreme highs by month, wind and storm variability, intensity and duration, calculated wind chill factors, and specific hazards associated with exposure to high winds (storms).
- 4. Solar Radiation mean and total number of sunshine hours by month and annually, duration of sunshine is of major importance for establishing summer and winter recreation capability.
- 5. Other Climatic Factors and Associated Phenomena rate and amount of evaporation, relative humidity, ice formation, thickness and duration, occurrence of fog, hail, and seasonal or unexpected storms, water and soil temperature regimes, snow avalanches and soil slumping or mass wasting, atmospheric pressure and density and the occurrence of frost.
- Source: Jurdant et al (1974); Verberg (1974); Jubenville (1976); Edmonton Region. Plan. Comm. (1977); Bennett (1977) and Alberta Rec. & Park (1979).

radiation) and wind to establish recreational suitability ratings. These four factors were chosen because they represent the climatological data currently available in B.C., i.e., they have been quantified, they have a direct influence on a range of recreational pursuits and their roles in climaterecreation interactions are fairly well understood.

When classifying areas as to their climatic suitability for recreation, it is important to consider the range of recreational activities and weather conditions which will affect their pursuit, the availability of climatic data, the seasonal variation of climatic conditions and the range of values of climatic parameters encountered over the entire area under study, e.g. province of B.C. Under Bennett's (1977) approach, each of the four climatic factors are defined and separated into suitability classes, with Class I being the most suitable and Class V being the least suitable for the pursuit of recreational activities (refer to Appendix III). Following a review of the site requirements for each of the selected recreational activities and the definitions of climatic factor suitability classes, the suitability classes were allocated into one of three generalized suitability categories, i.e., none-slight, moderate or severe. As an illustration of this procedure, refer to the following excerpt from Table 5: (p. 72): Ecological (Biophysical) Limitations for Camp Areas (Intensive Use):

Once the suitability classes of each of the four climatic factors have been assigned to one of the three generalized suitability classes these generalized classes are then used to classify areas for recreational suitability based on the degree of limitation each climatic factor has on the activity(s) being evaluated.

- 71 -

Excerpt from Table 5:

| | Degree of | Limitation ¹ | |
|-----------------------|-----------------|-------------------------|----------------------|
| Item Affecting Use | None- Slight | Moderate | Severe |
| Climate ² | | | |
| Temperature | Class l | Class 2h or 2k | Class 3h, 3k, 4k, 5k |
| Precipitation | Class l | Class 2 or 3 | Class 4 or 5 |
| Wind | Class l | Class 2 or 3 | Class 4 or 5 |
| Sunshine | Class l | Class 2 or 3 | Class 4 or 5 |

Refer to Section 3.8 for definitions of none-slight, moderate and severe limitation classes.

² Source: Bennett (1977). Camping (intensive) is classified as a land-passive summer/transition activity. Refer to Appendix III for a summary of the climatic criteria used to derive suitability ratings and for definitions of each of the climatic factors of temperature, precipitation, wind and sunshine.

3.6.1 Climate of Clague Mountain Park

No specific climatic data are available for Clague Mountain Park. However, it is possible to gain insight into its climate by referring to the park's Biogeoclimatic Zones, data collected by Environment Canada for Kitimat (Envir. Can., 1975a, 1975b and 1976), and Bennett (1976), on the subalpine and alpine zones of British Columbia.

The park's climate is marine mesothermal or mild microthermal humid to rainy, with slight to moderate snow cover, in the lower elevation Coastal Western Hemlock Zone; microthermal subcontinental (subalpine) humid, with heavy snow cover, in the mid-elevation (305 to 762 meter) Mountain Hemlock Zone; and alpine tundra in the higher elevation (greater than 900 meter) Alpine Zone (Appendix II). The park has wet autumns and dry summers, with 30 to 40% and 10 to 15%, respectively, of the total annual precipitation occurring during these periods.

In the subalpine and alpine environments the precipitation generally increases with increasing elevation, with maximum amounts occurring at the base of clouds (Bennett, 1976). Subalpine and alpine areas usually have colder annual minimum temperatures, lower maximum temperatures and diurnal ranges which are less than adjacent lower elevation areas due to stronger winds and the lower density of the atmosphere. Air temperatures at high elevations tend to decrease with elevation at an average rate of 5 to 6°C per 1000 meter rise in elevation. The combined influence of lower temperatures and increased precipitation result in increased snow accumulations. Winds are usually stronger and more persistent at higher elevations. Wind plays a major role in the clearing and transporting of snow, and, when combined with the influence of local topography, it determines the distribution of snow. At higher elevations the atmosphere is, generally, thinner, cleaner and drier resulting in a decreased amount of radiation scattering, increased levels of incoming ultraviolet radiation, extreme nocturnal cooling at the surface and harmful affects on vegeta-

- 73 -

tive cover, especially those species located within one meter of the surface, i.e., surface species are subject to extreme diurnal temperature variations.

The climate of the lower elevations of the park (sea level to approximately 300 meters) can be inferred from meterological data collected at Atmospheric Environment Service (A.E.S.) climate stations located along the Kitimat-Terrace Valley. The climatic data collected at the Kitimat Townsite A.E.S. station was deemed appropriate due to its close proximity to the park, its extended period of data collection and the diversity of climatic information collected and readily available relative to the other A.E.S. stations in the valley. Table 4 summarizes the climatic parameters of temperature, precipitation (rain and snow), sunshine and wind specific to the Kitimat Townsite A.E.S. station.

The foregoing climatic data is representative of the lower elevations of the park, with notable differences between this data and the actual climatic conditions found within the park arising due to variations in slope, aspect, elevation, nature of the dominant air masses and cloud conditions. As climate will play a major role in determining the suitability of the park for the set of recreational activities, it is important that it be adequately inventoried, assessed and incorporated into the overall site planning and development process.

 Abbreviation "M" represents missing data.
 Total precipitation is the sum of the rainfall plus the water equivalent of the snowfall, which is normally obtained by dividing the snowfall amount by 10, i.e., 10 cm of snow (uncompacted) is approximately equivalent to 1 cm of water.
 Source: Environment Canada (1975c).
 Indicates that for 33% of Oct. the wind was from the north at 13.2 km/hr and for 32% of Oct. the wind was from the south at 12.6 km/hr.
 Indicates that for 27% of the year the wind was from the north at 13.5 km/hr and for 43% of the year the south at 12.1 km/hr.

3.7 Unique Site Features

Unique site features refer to those ecological parameters which aid in establishing the suitability of a site for recreational activities but have either not been previously dealt with or have received only a broad, cursory treatment. These features are meant to elaborate on and/or introduce concepts different from those discussed in conjunction with landform and parent material, topographic relief, soil moisture regime and drainage, texture, permeability, stoniness, rockiness, depth to bedrock or impervious layer, frost action, erosion hazard, flood hazard, vegetation and climate.

Mountain climbing is one activity that can illustrate what is meant by "unique site features" and how they aid in establishing the suitability of a site for this activity. Areas that have none-slight limitations (good suitability) for mountaineering are characterized by rock structures which are firm and stable, being igneous (granite or grabbo) or metamorphic (gneiss or schist) preferrably, concave sites with low (velocity) winds, and rock types that possess an abundance of cracks and fractures, and are typically rough textured. At the other extreme, areas that have severe limitations (poor suitability) for mountaineering are characterized by crumbly, unstable rock types such as sedimentary rock (sandstone or limestone), unstable glacial detritus and recent volcanic materials, convex sites with evidence of high winds, areas with active surface seepage and/or runoff (water), areas that

- 76 -

are known or suspected of being of high avalanche and/or rockfall hazard, and areas with smooth, well-weathered rock types devoid of "hand-holds" and/or covered with a thin mantle of turfy vegetation.

3.8 Site Limitations for Selected Recreational Activities

The ecological parameters previously discussed were used to describe the site limitations for the selected recreational activities. The suitability of a site for these activities will also be dependent on the nature of the activity, season of participation, size of user groups and other factors of supply and demand.

Various authors provide insights into the limitations posed by the site parameters on the selected recreational activities (Archer, 1963; Montgomery and Edminster, 1966; Brooke <u>et al</u>, 1969; Murray <u>et al</u>, 1971; Denney, 1972; Culbert, 1974; Hawes, 1974; Verburg, 1974; Fogg, 1975; Vold, 1975; Eekman, 1976; Jubenville, 1976; Min. of the Envir., 1976; Bennett, 1977; Alberta Rec. & Parks, 1979). Tables have been drawn up which summarize each activity's ecological site limitations. The parameters selected are those factors of the environment which were likely to influence the type and intensity of recreation use. Ecological parameters used to evaluate an area for a specific activity are ranked as being of none-slight, moderate to severe limitation for the intended recreation use. Suitability classes are defined as follows:

- None to Slight Limitation a rating of none to slight (good suitability) indicates that if there are limitations (as indicated by deviations about the site requirements) they will be generally easy to overcome without special planning or management procedures.
- Moderate Limitation a rating of moderate (moderate suitability) indicates that the limitations identified can generally be overcome with good planning, design and/or management at a moderate cost.
- <u>Severe Limitation</u> a rating of severe (poor suitability) indicates that even with good planning and management the limitations will be difficult to overcome. Areas with severe limitations are generally unsuitable or require special and often costly procedures to make them suitable for a specified recreation use.

The choice of activities was made on the basis of what major recreational activities were actually occurring or would most likely occur within and adjacent to Clague Mountain Park. Determination of an area's suitability for one or more of the aforementioned recreational activities was made on the basis of the previously discussed ecological parameters and their associated degrees of limitation for each of these activities. As a result of an extensive review of the literature, Tables 5 to 13 were derived.

| Items Affecting Us | e ^{1.} | Degree of Limitation | |
|---|--|---|---|
| | None-Slight | Moderate | Severe |
| Soil Moisture & Drainage ^{2.} | Well to moderately well drained soils with no ponding. Depth to watertable should be sufficient so as not to adversely affect use and/or construction. Very dry (xeric) to moderately dry (subxer- ic) moisture regime. | no ponding. Mesic moisture regime. | Well drained, moderately well drained and somewhat poorly drained, with infrequent ponding of short duration; poorly and very poorly drained soils. Hygric to hydric moisture regime. |
| Surface Soil Texture ^{2.} | Moderately coarse to medium text- ured soils; sandy loams to loams; soils not subject to blowing. (sl,fsl,vfsl,l and ls). Fertile soils containing a high % of medium-coarse textured soil mat- erial and high in organic matter as well. | Coarse textured soils; loamy sands (1s) not subject to blow- ing; medium to moderately fine textured soils; silt loams (sil) to silty clay loams (sicl). (cl,scl,sicl,sil,ls, and s) | Fine textured soils; clays with poor permeability; loose sands (s) with low cohesion, soils subject to blowing or with unstable surface. (organic, c,sic,sc, and loose s) |
| Permeability ^{2.} | High to moderate (.5cm/hr to .5 - 5.cm/hr) | Moderate (.5 to 5.cm/hr) | Poor (0 to .5cm/ht) |
| Stoniness ^{2.} | .01% of surface occupied by rock fragments 15cm (6in) in diameter. Non-stony. | .01 - 3.% of surface occupied by rock fragments 15cm (6in) in diameter. Slightly to moderately stony. | 3 50.% of surface occupied by rock fragments 15cm (6in) in diameter. Very to excessively stony. |
| Rockiness ² . | .01% of surface occupied by exposed bedrock. Non-rocky. | .01 - 3.% of surface occupied by exposed bedrock. Slightly to moderately rocky. | 3 50.% of surface occupied by exposed bedrock. Very to excessively rocky. |

Table 10 : Ecological (Biophysical) Limitations for Snowmobiling

| Items Affecting Use ^{1.} | | Degree of Limitation | |
|---------------------------------------|--|---|---|
| | None-Slight | Moderate | Severe |
| Slope ² . | $0 - 8$ % ($0 - 4.6^{\circ}$) may vary depending on snow conditions. | 9 - 15% (5.1 - 8.5 ⁰) with a maximum sustained gradient of 15% (8.5 $^{\circ}$). | 16%+ (9.1 $^{\circ}$ +) For short pitches gradient of climb ranges from 20 to 25% (11.3 - 14.0 $^{\circ}$). |
| Aspect ^{3.} | N, NW, NE or level for snow accum- ulation and shade "effect". In more northerly latitudes and/or at higher elevations warmer south facing aspects may be preferred. Varied aspect provides for a more enjoyable experience. | W, E, OT SE. | SW or S due to prolonged exposure to the direct rays of the sun, resulting in snowmelt and/or ground exposure. |
| Unique Site Seatures ^{2.} | Flat, stable surficial deposits. Level to rolling topography. No natural and/or man-caused obstac- les. Absence of flora and fauna susceptible to snowmobile damage and/or disturbance. | · | Alpine meadows, avalanche hazard areas, cliffs and other steep terrain, thermal pools, road crossings, areas of wildlife concentration, (including subnivean flora and fauna), lake and stream crossings, wetland areas; forest plantations, fences guy wires, and all other natural and/or man-caused hazardous areas. |
| Vegetation 2. Sensitivity | Grasses and other species resist- ent to compaction and resultant reduced growing season and deep freezing effects; species with deep root systems that aid in thei survival; species with fast rates of succession and high resilency to adverse useage. | r ک | Shrubs, saplings, and other vegetation adjacent to trails and subject to mechan- ical damage; reduced growing season and deep freezing effects due to snow compac- tion are especially critical in high alpine areas; species with low rates of succession, shallow root systems and fragile vegetative structures may be totally eliminated. |
| Density ^{4.} | Low density to open areas that all for ease of movement over and/or through vegetation cover, eg. lod pole pine and aspen cover (mature) | je- | Dense under- and/or overstory vegetation types that makes access virtually impos- sible, eg. alder, willow, and salmon- berry bushes adjacent to streams. |
| Height ⁵ . | Cleared of vegetation overhang to height of greater than 10 ft (3 m) | alcieared of vegetation to | Less than 8 ft (2.4 m) clearance between • vegetation overhang and top of snow. |
| Height ⁶ (Tree) | Over 20 ft (6.1 m); will vary depending on species, density, snowpack depth, and other site factors. | | Less than 10 ft (3 m) (rough estimate) |

Table 13 : Ecological (Biophysical) Limitations for Trails (Summer Use)

| Items Affecting Us | se ¹ . | Degree of Limitation | |
|--|---|---|--|
| ••••••••••••••• | None-Slight | Moderate | Severe |
| Soil Moisture & Drainage ² | Well to moderately well drained soils. Very dry (very xeric) to mesic moisture regime. | Well to moderately well drained soils subject to seepage or pondin and somewhat imperfectly drained soils. Mesic to hygric moisture regime. | Poorly to very poorly drained soils g subject to ponding. Hygric to hydric moisture regime. |
| Surface Soil Texture ² | Moderately coarse to medium textured soils; sandy loams to loams. (sl, fsl, vfsl, and l). Gravelly and non-gravelly soils. | Medium to fine textured soils; silt loams to sand clays; loamy sands. (sil; sicl, scl, cl, sc, and ls). | Fine textured soils: clays; loose sands and soils subject to blowing. (sic, c, and s). All soils that are very gravelly composed of very thin and flat coarse rock fragments and/or very cobbly. Organic silts, silt-clays and clays; peat and other highly organic soils. |
| Permeability ^{2.} | High to moderate (5.cm/hr to .5 - 5.cm/hr). | Moderate (.5 - 5.cm/hr). | Poor $(05cm/hr)$. |
| Slope ^{2.} | $0 - 30.8 (0 - 16.7^{\circ})$ level to steeply sloping. | 30 70.% (16.7 - 35.0 ⁰) steep to very steeply sloping. | 71.%+ (35.4 ⁰ +) extremely sloping causing movement to be slow and extremely hazard- ous. |
| Aspect ² | S, SW, SE, E, W, and level. Variety of slope orientations is desired. | N, NW, and NE aspects can result in cooler, less favourable conditions especially in winter. | No aspect poses severe limitations for paths and trails (summer use). |
| Erosion Hazard ^{3.} | Low (stable) | Moderate (metastable) | High (unstable) |
| Frost Action ^{3.} | Low (rated as moderate in alpine zone or subalpine krum- mholz zone) | Moderate (rated as high in alpine zone or subalpine krummholz zone or when imperfectly to poorly drained) | High |
| Flooding ² . | No to rare occurence during season of use; being of nil to slight flood hazard. | Regular light flooding may be expected during season of use; being of moderate flood hazard. | Irregular, moderate to heavy frequent flooding during season of use; being of severe flood hazard. |
| Unique Site Features ⁴ | Trail should allow for variety of experiences: panoramic views, benches, ridges and valleys, open spaces, forested areas, high point away from development, exposure to unique communities, and run along water bodies. | area is maint ous areas suc and damaging hazardous res ecologically unique flora mountain lake | ant that the ecological integrity of the tained by avoiding unstable, hazard- th as creek bottoms subject to sudden floods, steep slopes, rock bluffs, and source use or extraction areas, and sensitive areas such as meadows, rare or & fauna, and shorelines around high es, swamps and boggy land, and ecological lected areas must be able to withstand |

anticipated use levels.

ł

66

| Items Affecting Use ¹ . | | Degree of Limitation | |
|--|--|--|---|
| | None-Slight | Moderate | Severe |
| Vegetation ^{2.} Sensitivity | Low sensitivity vegetation type with fast rate of succession. | Medium sensitivity vegetation type with moderate rate of suc- cession. | High sensitivity vegetation type with slow rate of succession. |
| Density | Low to medium density not posing problems to movement, eg. moss, and small scattered shrub under- growth in old growth sitka spruce forest. | Medium density, eg. confferous (forest with vaccinium understory) | Medium to high density; significantly impeding movement, eg. salmonberry bushes along stream bank. |
| Height | Low underbrush absent or such that movement is not impeded. | Low underbrush and shrub vegeta- tion impedes movement. | Vegetation drastically hinders movement and significantly reduces the amount of direct sunlight. |
| Plant Association | | | |

- 102 -

Having previously identified the criteria often used to inventory, classify and assess distinct ecological landform units and the site limitations of the selected recreational activities, this section presents an approach which facilitates assessment of an area's suitability for the selected recreational activities. The approach can be used to identify parcels of land that are homogeneous, i.e., distinct landform units, as well as rate these parcels as to their intrinsic suitability for each of the nine selected recreational activities.

The approach selected is based on the "rules of combination" approach to land suitability analysis and the generation of land suitability maps as discussed by Hopkins (1977). The reasons for selecting this approach are that,

- it can handle the interdependency which exists among factors, i.e., ecological parameters used to establish recreational suitability,
- it provides for explicit identification of regions
 (distinct landform units),
- and, it also provides for explicit determination of ratings, i.e., establishment of suitability ratings for each landform unit on the basis of site requirements of the recreational activities, as described in the context of a set of significant ecological criteria.

The rules of combination approach assigns suitabilities to

sets of combinations of types, i.e., ecological criteria, rather than to single combinations. Rules are expressed in terms of verbal logic rather than in terms of numbers and arithmetic, as is the case for other approaches to land suitability analysis (Hopkins, 1977).

The first step in the analysis is to establish a set of relevant ecological parameters for each of the selected recreational activities. These parameters serve to describe the natural environment and facilitate the determination of the suitability of specific areas for one or more of the selected recreational activities.

In order to provide a stable, readily identifiable base upon which to inventory, classify and assess the parameters, the area under study is broken down into distinct landform units using the Terrain Classification System approach to landform analysis (Min. of the Envir., 1978). This constitutes the second step of the analysis. Ground checks and the use of airphoto interpretation will improve the accuracy and speed with which this procedure is undertaken. The product of this procedure is a base map showing the spatial patterns and distributions of the distinct landform units.

The third step in the analysis, is the derivation of resource factor maps using the environmental parameters relevant to the recreational activities under consideration. Factor maps should be at a common scale and format. The scale, format and detail of the derived maps will be dependent on the

- 103 -

objectives of the study, the availability of existing information and other factors which will influence the intensity, scope and detail of the land suitability analysis procedures. Factor maps should be on stable transparent material, e.g. mylar, permitting ease of viewing and the establishment of the suitability of delineated landform units for one or more recreational activities. Figures 14 to 16 are schematic illustrations of slope, aspect and soil moisture regime factor maps.

The fourth step entails overlaying each factor map, one at a time, onto the base map, then summarizing, in tabular and map formats, the inherent ecological characteristics of each landform unit previously identified on the base map. Figure 17 illustrates this procedure.

Once all landform units have been assessed as to their inherent ecological limitations, they are rated for their suitability to sustain the selected recreational activities. In Section 3.8 the tables listing the ecological limitations for each of the nine selected recreational activities are used to establish the overall suitability of a landform unit for each activity. Environmental parameters which pose severe limitations (poor suitability) for one or more specific recreational activities, generally override the ratings given to all other parameters of the same landform unit. For landform units where the limitations posed by a specific environmental parameter is borderline between two degrees of limita-

tion (none-slight to moderate or moderate to severe) a review of the limitations posed by all environmental parameters will be necessary prior to establishing a generalized composite suitability rating of each landform unit, for each recreational The environmental parameters used to establish the use. suitability of landform units for the selected recreational activities, are not equally influential in establishing a landform unit's suitability. When considered in aggregate, they (the parameters) provide an indication of the overall suitability of landform units for specific recreational activities. Using this approach to land suitability analysis a summary table is formulated to show the generalized suitability ratings of landform units and their associated limiting factors. A second outcome of this approach is a set of maps, one for each recreational activity, showing which level of suitability characterizes each landform unit or grouping of landform units. No attempt is made to account for the intercompatibility of the various recreational uses. The suitability of each landform unit, for each recreational activity, is derived from assessments of the capability of the environmental features of the landform unit to sustain a particular use, as well as on the requirements and characteristics of each recreational use.

- 108 -

3.10 Survey and Mapping Methodology

For the purpose of this study, the ecological information, required to establish the suitability ratings of the park for each of the nine selected recreational activities, was inventoried, classified and interpreted on the basis of the integrated approach to ecological land classification (ELC) as discussed in Section 2.4.

The Terrain Classification System approach to landform classification and analysis (Min. of the Envir., 1978) was used to subdivide the park into discrete terrain units, i.e., landform units, thereby providing a base upon which relevant ecological parameters could be interpreted and from whence could be derived generalized suitability ratings of each unit for each of the nine selected activities (Figure 5). The characteristics of the Biogeoclimatic Zones found within the park (Appendix II) provided clues as to the suitability of each of the three zones for the set of activities. Through the combined use of airphoto interpretation, ground reconnaissance data and relevant reports and publications, the aforementioned ecological parameters were identified, mapped and tabulated for the entire study area (refer to Figures 7, 8, 11, 12 and 13).

Once the park had been classified and mapped using the selected ecological parameters, the delineated landform units were assessed, in terms of each of the selected parameters, using a map overlay approach, with the findings of this assessment being summarized in a tabular format. The final step in this approach to recreational site suitability analysis entailed assessing each landform unit as to its suitability, i.e., poor, moderate or good suitability rating based on the degree of limitation, for each of the nine recreational activities using the activity-specific ecological limitations discussed in Section 3.8. The results of the generalized suitability analysis, in the form of both tables and maps, could then be used, at some time in the future, to aid in the establishment of land use and general site development plans for the park.

4.0 LANDFORM UNIT DESCRIPTIONS AND SUITABILITY RATINGS FOR SELECTED RECREATIONAL ACTIVITIES

Twenty-three different landform units were delineated within Clague Mountain Park. The general categories identified were comprised of landform units originating from colluvial, fluvial (alluvial), morainal, organic, and bedrock parent materials. Table 14 summarizes the ecological characteristics of each landform unit and includes information pertaining to the area (hectarage) and range of elevations over which each landform unit extends. Table 15 provides a summary of the generalized suitability ratings for each landform unit for the set of selected recreational activities. Figures 18 to 26 illustrate the generalized suitability ratings that are indicated in Table 15. In the construction of the aforementioned

maps, landform units of identical suitability rating, for a given recreational activity, were aggregated in an attempt to provide a practical final product that readily conveys the findings of the suitability analysis and facilitates ease of future application, e.g. land use and site development planning. Refer to Appendix VII for photographs which are representative of each of the delineated landform units. Unfortunately, photographs illustrating the $F^{A}a - E$ (fluvial), $M^{I}bh$ (morainal), $\frac{M^{I}v}{R}$ (morainal) and $\frac{O^{B}v - N}{Rh}$ (organic) landform units are not available for inclusion in Appendix VII. Water bodies, in the form of lakes and small ponds, were also identified but not rated as to their suitability and/or capability to attract and sustain recreational activities.

5.0 SUMMARY AND RECOMMENDATIONS

On the basis of the preceeding recreation suitability analysis it was found that:

- Camping (intensive) is best suited to five landform units, i.e., F4, F5, M2, M5 and O2, which are located southwest of Bowbyes Lake and in the subalpine areas adjacent to the Main Meadow area.
- 2. Hiking (summer) is suited to most areas of the park being severely limited in areas of subalpine meadow (Main Meadow area), as well as the lower elevation marshlands adjacent to Bowbyes Lake.
- 3. Downhill skiing is classified as having a poor to

- 124 -

moderate suitability rating for most landform units, with severe limitations (poor suitability) for this activity existing in areas with excessively steep slopes, e.g. Cl, areas that are level and subject to flooding and have high water tables, i.e., fluvial landform adjacent to Bowbyes Lake, and in high elevation subalpine meadows.

- 4. Cross-country skiing is best suited to landform units that are level to rolling and characterized by open to somewhat scattered vegetation types that pose minimal limitations to movement on the ground, such units being adjacent to Bowbyes Lake, the Main Meadow area and, if snow conditions are right, the high elevation bedrock landform units.
- 5. Snowmobiling is best suited to the mid-elevation level to gently sloping morainal landforms and the fluvial landforms south and southwest of Bowbyes Lake. All other landform units are moderately to severely limiting for snowmobiling due predominantly to the existence of steep slopes or specific vegetation types. Due to the limited space suitable for recreational development within the park, it is imperative that snowmobiling be adequately integrated into the overall land use planning and development of the park, so as to minimize user conflicts and the impacts of snowmobiling upon the plant and animal communities contained within the park.

- 6. Snowshoeing is best suited to areas of low slope gradient and areas characterized by vegetation which does not hinder movement. Such areas include the landform units situated adjacent to Bowbyes Lake, those within the subalpine meadow areas and those found in the higher elevation bedrock areas of the park. If the latter area proves to be too exposed and/or lacks sufficient snow cover, snowshoeing should be restricted to lower elevation areas of moderate to good suitability, i.e., of moderate to slight limitation for snowshoeing.
- Tobogganning is best suited to the lower elevation glacio-7. fluvial landform unit on the east side of the park, the area of hummocky morainal deposition found south of Bowbyes Lake, and the level to gently sloping glaciofluvial fan situated southwest of Bowbyes Lake. Although the suitability analysis indicated that the high elevation bedrock areas, i.e., Rr-C(N) and Rh-C(N), were of moderate to poor suitability for tobogganning, access into these areas and problems with excessive exposure to winds and direct sunlight warrants that greater consideration be given to lower elevation landform units exhibiting more favourable site characteristics. Areas of steep terrain, dense vegetation and/or subject to flooding or high water tables pose severe limitations for this recreational activity. Toboggan runs should be planned and developed in conjunction with other winter-

based recreational activities.

- 8. Mountain climbing (mountaineering) is best suited to the most westerly fringe of the park, in areas of exposed bedrock and steep cliffs typical of the colluvial landform units found within the park.
- 9. Picnicking and day use activities are best suited to the level to gently sloping morainal (M4) and fluvial (F5) landform units found immediately west and south of Bowbyes Lake, as well as the 02 organic landform unit adjacent to the Main Meadow area. Prior to developing these areas for picnicking and day use activities it is stressed that more indepth studies by undertaken pertaining to the soils, climate, hydrology, and wildlife communities characteristic of these areas. It should be noted that the generalized suitability map drawn up for picnicking and day use activities corresponds very closely to that established for campgrounds, hence these two activities should be considered together in any future park planning and development.

The following recommendations are based on ground reconnaissance of the park and the findings of the recreation suitability analysis:

 It is essential that, in anticipation of the increased demand for recreational opportunities in the Kitimat-Terrace area, the existing access road to the park and the trail network within the park be upgraded. Upon examination of the existing trail system it was found that: areas of extensive blowdown seriously hindered movement along the trail, the "forest of snags" first encountered as one enters the park from the east, poses a serious threat to the safety of park users, and there is a need to relocate certain segments of the trail in an effort to avoid areas of high water table, e.g. peat bogs, specific vegetation types, and excessively steep slopes subject to erosion. If trail relocation is deemed inappropriate, time and monies should be spent to build structures suitable to minimize the impact of man upon the plant and animal communities found within the In addition, it was found that no system of trail park. signs existed within the park. Trail signs located at trail heads and along trail routes are invaluable for providing the user public with information pertaining to specific trail features, points of interest, access, length, location of route, degree of difficulty and time to traverse.

2. It is recommended that the "forest of snags" be either felled and bucked, i.e., cut into short sections, completely or, at the very least, selectively cut down and bucked over a sixty metre wide swath on either side of the trail, for the length of trail running within this "forest of snags".

3. It is recommended that conflicts between mechanized and

- 128 -

non-mechanized trail activities should be dealt with by formally designating separate trails and areas for snowmobiles, trail bikes, A.T.V.'s, hiking, cross-country skiing, snowshoeing, and other activities which may lead to user conflicts. Management techniques must be implemented to resolve conflicts arising between or amongst non-compatible recreational uses.

- 4. It is recommended that user groups, local resource extraction and manufacturing industries, municipal and regional governments, and all other interested citizens be involved in the overall planning, development, management and maintenance of this rather beautiful, yet sadly neglected park that is situated at the "doorstep" of Kitimat.
- 5. It is recommended that in the planning and execution of forest extraction activities by Eurocan Pulp and Paper Co. Ltd. north of the Bowbyes Lake area, every attempt be made to insure that the natural integrity and general sense of "wilderness" be maintained in this, as yet, untouched portion of the park.
- 6. It is recommended that the Corporation of the District of Kitimat become more involved in the overall management and planning of Clague Mountain Park, by way of enforcement of the established regulations governing park use, upgrading and maintenance of access roads and the existing trail network, and allotment of time and monies

to facilitate a detailed inventory and analysis of the ecological (biophysical) attributes of the park, as well as the determination of the current and anticipated recreation demand on the park.

7. It is recommended that the findings and general suitability ratings of this recreation suitability analysis be used to assist in any future recreation planning and development within the park. The results of this study would be of use in the preliminary stages of park planning and development. If more detailed, site-specific information is required, it is recommended that more indepth studies be initiated.

The approach presented in this thesis is not new. The amalgamation of activity-specific ecologically significant criteria into condensed tables represents summaries not frequently found in the literature. This approach represents one of several approaches that will facilitate a systematic assessment of land units' capabilities to support selected recreation activities. Others include the Canada Land Inventory and the B.C. Resource Analysis Branch approaches to recreation capability assessment.

This approach should be used in conjunction with traditional "on-site" assessments made by experienced field personnel. It is believed the approach presented in this thesis will aid in the identification of potential problem areas, i.e., ecological, social and/or economic, early in the

- 130 -

planning stages. As the planned costs associated with facility development increase there will be an ever increasing need to use better, more sophisticated interpretative "tools", this approach being one of them. In conclusion the author believes the approach to recreational site-suitability analysis presented in this thesis is suited for undertaking reconnaissance level inventories and analyses of the recreational capabilities of areas in the Coast Mountain region of B.C.

APPENDIX IV

Detailed description of Clague Mountain Trail (*after Blix (1977))

,

Clague Mountain Trail [KT2]

GENERAL AREA: Kitimat-Terrace, near Kitimat

MAPS REQUIRED:

1031/2W Kitimat (1:50,000) 1031/2E Kitimat (1:50,000) 1031 Terrace (1:250,000)

TRAIL DESCRIPTION:

About 41/2 miles from the start of the trail at elevation 100 ft. to Claque Mountain, elevation 4400 II. A well defined trail all the way, but extremely muddy in sections. The first mile or so is a logging road and the next 1/2 mile is a cat road that goes through a slashed area. This was originally cleared for a skihill, but never used. The slashing is very steep with a gain in elevation of about 1000 ft. in a 1/2 mile. The trail then flattens out for a short distance and traverses a marshy area. After skirting around a small lake, it immediately climbs steeply a couple of hundred feet to another marshy, gently sloping area. At the top of this slope, the trail enters a distinct valley. The elevation at this point is approximately 2000 ft, and the distance from the starting point about 2 miles.

The most used summer route continues more or less westerly, and climbs steeply up beside a creek (true right bank). At the top of this slope, the trail emerges into an open gently sloping valley, at elevation 2700 ft., which is about timberline near the coast. From there after crossing the creek, the trail gradually climbs up onto a ridge to the right (north) and follows this to the summit. A higher summit (4500 ft.) is reached by following the ridge as it continues northwesterly for about a mile.

A more pleasant and far easier winter route can be found by bearing left (southwest) up the valley instead of taking the steep summer route straight ahead. This route follows the valley up, gradually climbing and bearing right (north). Where this route eventually climbs out of the valley, the timber is quite open and poses no problem for skiers. After emerging from the valley, bear left and follow a subsidiary spur in a westerly direction up onto the main, southeasterly ridge of Claque Mountain and follow it to the summit.

Allow 4-5 hours from the start of the trail to the summit, and 2-3 hours down.

DIRECTIONS:

After crossing the Kitimat River bridge on Hwy 25 (Haisla Blvd.). continue straight on to Enterprise Ave, then turn right (north) and drive along Enterprise which shortly turns telt (west) and crosses the CN tracks. Just beyond, at the intersection with the logging road, turn right again and continue along the logging road in a northerly direction for just under a mile. Where the logging road makes a distinct right turn, turn left onto a side road. This side road is fine for about a mile which is where the cat road starts off straight ahead up the slashed area.

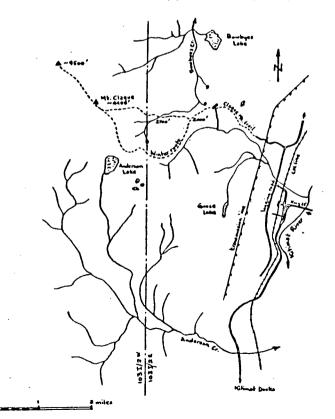

COMMENTS:

This trail gives very convenient access to alpine country for anyone living in or visiting Kilimat. It is a steep, muddy and somewhat unattractive route for the first couple of miles, but beyond that there are good views and pleasant alpine terrain. Once above timberline, there is easy access to a considerable area of good hiking and ski touring country.

As far as skiing is concerned, the problem is getting up and down the steep portion at the start. Except under extremely good snow conditions, most people will find it easiest to carry their skis both up and down this section.

It is recommended that this trail be used only when the wind is from the north; otherwise the fumes from the smelter and pulpmill detract significantly from one's enjoyment.

Young children and even older ones without previous hiking experience generally do not find this trail enjoyable due to steep muddy parts.

APPENDIX V

Clague Mountain Park Regulations

.

0

THE CORPORATION OF THE DISTRICT OF KITIMAT

BY-LAW

CLAGUE MT. MUNICIPAL PARK - REGULATIONS

BACKGROUND

THE CLAGUE MOUNTAIN AREA WAS LEASED FROM THE CROWN IN 1963 ON A 21 YEAR LEASE AT AN ANNUAL RENT OF \$185.50*. (SEE ATTACHED SKETCH.)

P'RPOSE

THE PURPOSE OF THIS REPORT IS TO SUGGEST CERTAIN REGULATIONS TO CONTROL THE USE OF THE PARK IN RESPECT TO VARIOUS ACTIVITIES SUCH AS TIMBER CUTTING, CABIN BUILDING, DISPOSAL OF REFUSE FIRE PREVENTION, PROHIBITION OF MUNTING, ETC.

RECOMMENDATIONS

THAT THE DRAFT REGULATIONS ATTACHED TO AND FORMING A PART OF THIS REPORT BE CONSIDERED FOR ACOPTION,

* THE RENT IS SUBJECT TO REVIEW AFTER A PERIOD OF FIVE YEARS.

PLANNING DEPARTMENT, REPORT NO. 6501, JALUARY, 1965.

A BYIAW to establish regulations for Clague Mountain Park.

WHEREAS it is intended that the land known as Clague Mountain Fark as leased . from the Crown under the terms of the "Park and Recreation Land Lease Eylaw No. 1, 1963, be established as a municipal park.

AND WHEREAS it is intended that Clague Mountain Fark be preserved and used as a wilderness reserve.

AND WHEREAS it is intended that Clague Mountain Fark remain a recreational area to be enjoyed by hikers, skiers and campers.

AND WHEREAS it is considered that regulations should be established to ensure the continued enjoyment of Clague Mountain Park for recreational purposes.

NOW THEREFORE the Council of the Corporation of the District of Kitimat, in open meeting assembled, amends the Kitimat Municipal Code by enacting the following:

- This Bylaw may be cited as the "Clague Mountain Park Regulations Bylaw No.1, 1965".
- 2. Part XI is amended by adding the following Division 2 :-

Division 2 - Municipal Parks

Subdivision 1 - Clague Mountain Park

Interpretation

3. 11,210 Within this subdivision "Park" means the area described within the Park and Recreation Land Lease Bylaw No. 1; 1963.

Designation

4. 11,211 The area as described in the lease executed between the Municipality and the Crown and as described within the Park and Recreation Land Lease Bylaw No.1, 1053 is herepy designated as a Municipal Park. BY-LAW NO.

Permitted Uses

5. 11,212 The following uses only shall be permitted within the Park:

(a) Skiing (b) Hixing (c) Recreation camping other than camping in trailers. (d) Activities normally associated with wilderness recreation with the exception of hunting. (e) Temporary concessions operated in conjunction with the permitted uses (a), (b), (c) or (d).

Permitted Structures

6. 11,213 No structure is permitted within the Park other than structures which are used or intended to be used in conjunction with the uses permitted under Section 11,212.

Permits Required for Structures and for Timber Cutting

7. 11,214 No person shall construct or occupy any structure for which a permit is required without obtaining a permit, and no person shall occupy, use, or continue to occupy or use any structure which was constructed prior to the coming into force of these regulations without obtaining a permit.

8. 11,215

-) Park use permits are required for the crection or use of the following structures:
 - (a) Any cabin, outhouse or shed.
 - (b) Any structure used in conjunction with a concession.
 - (c) Any structure erected in conjunction with the operation of a ski tow.
- (11) No person shall cut any green timber for personal use without obtaining a timber cutting permit and paying stumpage charges as determined by the Crown.

Condition of Issuance of Permits

- 9.11,216 (1) Any permit for a concession shall be temporary only and in no case shall it be valid for more than twelve months from the date of issue, but may be renewed.
 - (11) No person shall lease, rent or charge a toll within the park unless such person has obtained a Fark Use Permit in which such lease, rent or toll is authorized.
 - (111) No park use permit issued for a concession shall be transforable.
 - (iv) The Authority Having Jurisdiction may impose conditions upon the issuance of any permit to control the location of any use or structure for which a permit is issued, to control the area from which trees may be cut by permit holders, and to ensure that dequate standards of cafety and health are observed.

BY-LAW NO.

Application for Permits

- 10. 11,217 An application for a permit shall be in writing, and shall include:
 - (a) The name and address of the applicant.
 - (b) A full description of the proposed use.
 - (c) The date upon which the proposed use is to commence.
 - (d) The date upon which the proposed use is to terminate.
 - (e) The approximate location of the proposed use within the park and details of any structures which are proposed to be built.
 - (f) Where the proposed use is a concession full details of proposed prices and admission fees, tolls or charges.
 - (g) Any other information which the Authority Having Jurisdiction may require.

Grounds for Refusal

- 11. 11,218 The Authority Having Jurisdiction may refuse to grant a permit for the following reasons:
 - If the location of the proposed structure or use will:
 - (a) Interfere with the use of existing or proposed roads, ski slopes or trails.
 - (b) Be likely to cause pollution of any lake or stream.
 - (c) Be in any way detrimental to the full enjoyment of any part of the park by the public.

Cancellation of Permits

- 12. 11,219 The Authority Having Jurisdiction may cancel any permit if the person to whom the permit was issued has:
 - (a) Failed to use the permit for the prupose for which it was issued within 6 months of the date of issue.
 - (b) Failed to comply with the conditions of the permit.
 - (c) Failed to comply with the regulations of this division.

3.

2.

BY-LAW NG.

Disposal of Improvements

- 13. 11,220 (1) Where a permit has expired or been cancelled any cabins or other improvements which have been constructed under the permit shall, within 60 days of the date of expiration or cancellation of the permit, be removed from the park or disposed of to the satisfaction of the Authority Having Jurisdiction.
 - (11) Where a permit holder has failed to remove or dispose of improvements to the satisfaction of the Authority Having Jurisdiction, within 50 days of the date of termination of his permit, the inprovements shall be forfeited and shall become municipal property, and the Authority Having Jurisdiction may order that they be disposed of in any way that he thinks is suitable.

Appeal to Council

14. 11,221 Any applicant of holder of a Park Use Permit may appeal to Council any decision by the Authority Having Jurisdiction pertaining to the refusal of a permit, the cancellation of a permit, the imposing of conditions upon the issuance of a permit, or the designation of areas where tree cutting is prohibited.

Zees

- 15. 11,230 The following annual fees shall be paid to the Authority Having Jurisdiction:

 - (c) Any other structure for which a permit is required. . \$ 10.00

Disposal of Sewage and Garbage

- 16. 11,235 (1) No person shall throw, place, discharge, or otherwise deposit any substance, matter, or thing in or near any watercourse or body of water, in the park, where such action might reasonably be expected to result in the pollution of water in the park.
 - (11) All sevage, refuse, garbage, waste paper, cans, bottles, or any other debris or discarded material shall be buried or destroyed.
 - (iii) All outhouses must be located at least 25 ft. from any habitable billing and have a pit 3 feet in depth or more. When abandoned the pit shall be filled with earth to original ground level and when in use it shall chemically treated or covered with soil daily.

BY-LAW NO.

4.

Tree Protection

- 17. 11,238 (1) No person shall take any timber from the park.
 - (ii) No person shall cut any green timber except for firewood or for constructing a structure for which timber cutting permit has been obtained as authorized under Sec. 11215 (ii).
 - (111) Notwithstanding Subsection (11) of this section, no person shall cut trees from any part of the park which may be designated by the Authority Having Jurisdiction as an area where the cutting of trees would interfere with the enjoyment of the park by the public.

Fire Regulations

- 18. 11,240 (1) Except in an approved cabin stove or in a portable camp stove no person shall start a fire anywhere in the Park for any purpose without obtaining a permit from the Fire Department
 - (11) No person, having started a fire for cocking or any other purpose, shall leave it without completely extinguishing it.
 - (111) No person shall discard any lighted cigar, cigarctte, match or any other burning substance anywhere within the park.
 - (iv) All indoor stoves must be provided with spark catchers and all heating equipment shall be subject to the approval of the Fire Department.

Roads and Parking

19. 11,242 No person shall park any vehicle on any existing or proposed road within the park in such a way as to obstruct the free passage of vehicles in either direction on any such road.

Firearms and Explosives

20. 11,244 No person other than an employee of the Provincial Fish and Game Department on duty, or a Police Officer on duty shall at any time have in possession within the park any firearm, gun, air gun, air rifle, air pistol, spring gun or explosive. BY-LAW NO.

6.

Game Protection

- 21. 11,246 (i) No person shall molest, pursue, hunt, shoot, trap, wound, capture, destroy, or in any manner interfere with or attempt to interfere with any animal or bird within the Perk.
 - (11) Ho person shall have any dead bird or animal in his possession within the Park.
- 22. This Bylaw shall take effect and come into force and be binding on all persons as from the date of adoption.

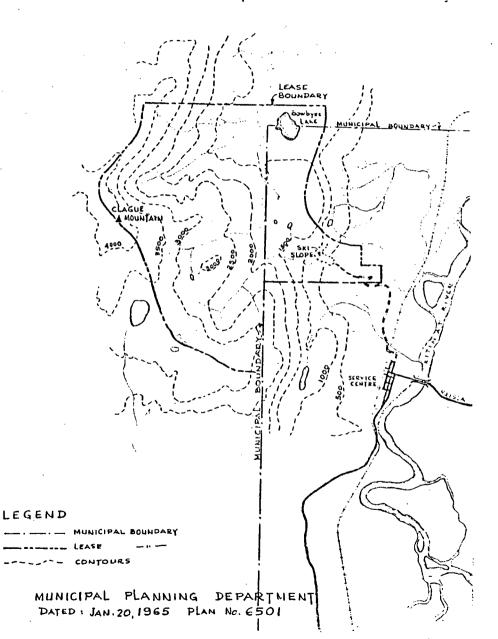

PECONSIDERED AND finally adopted by the Municipal Council of the Corporation of the District of Kitimat this _____ day of ______ 1965.
